INDEX TO VOLUME II., 1923.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c. (Py Q) = Parliamentary Question. (R.) = Review. (L. A.) = Leading Article.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

Abderhalden, Prof. Dr. E., Examination of Organs of Sense (R.), 1085 : Biological Technique (R.), 1305
Abdomen, Acute, Early Diagnosis of (Mr. Z. Cope), 2nd ed., 1923 (R.), 520
Abdominal pain, chronic, in nervous women, 1347
Abdominal Surgery for Nurses (Mr. H. Burrows), 2nd ed., 1923 (R.), 1086
Aberdeen Medico-Chirurgical Society (see Med. Socs.)
Aberdeen University, pass-lists, 147, 312
Abortion, criminal, alarming increase in Austria, 1320
Abrahams, Dr. A., treatment of chronic colitis, 1411
Abscess, brain (Dr. G. Hadfield), 929 ; perinephric, 1140 ; liver, treatment by aspiration, 1324 ; (Dr. A. R. Neligan), 1398
Accidents du Travail (Léon Imbert and others), 2nd ed., 1923 (R.), 609
Acclimatisation, problems of (Dr. A. Balfour), 84, 243
Account-keeping, medical, simplified, 492
Acid-fastness, 78, 97
Acidosis and alkalosis in children, 360
Acromegalic stigmata, distribution of, 662
Acrostic, a double, 914
Actinomycosis, ætiology of (Mr. W. T. Warwick), 497 ; of head and neck, 1408
Acts, delay in publication of, 796
Adams, Dr. D., disseminated sclerosis, 1033
Adams, Dr. E. W., and Dr. H. N. Crossley, acute goitre in a children's home, 501
Advertisement, a criticised, 1118
Advertisements on medical certificates (Py Q), 310
Agar-agar, 1200
Agassiz, Dr. C. D. S., and Dr. S. R. Gloyne, tuberculosis in childhood, 25
Agate, Dr. H. St. A., pathological departments, 586
Age, A Green Old (Prof. A. Lacassaigne) (R.), 656
Air Force Medical Service (see Students' Guide), 422 ; the, nature and use of, 636
Albuminuria with unilateral œdema (Dr. J. W. Russell), 925 ; of pregnancy, 1008, 1057, 1110, 1133, 1210
Alcohol, Action of, in Man (Prof. E. H. Starling) (R.), 982, 1055
Alexandra Day at Brighton and Hove, 486
Alimentary secretion, mechanism of (L.A.), 288
Allbutt, Sir C., and Dr. P. C. Varrier-Jones, village settlements for the consumptive, 912
Allbutt, Sir C., integration of medicine, 977 ; opium in cardiac dyspnœa, 1422
Allott, Mr. E. N., lilliputian dosage, 631
Alpine therapeutics, post-grad. course on, 27
Alunozal, 1358
Ambulance, authority to engage, 89
American Posture League, 1003
Amœbiasis, pulmonary (Dr. P. Manson-Bahr), 599
Anæmia, secondary, in infancy (Dr. Helen M. M. Mackay), 165 ; pernicious (Py Q), 208 ; splenic, 290 ; sickle-cell, 1363
Anæsthesia, endotracheal insufflation, expiration in (Dr. I. W. Magill), 68 ; for children, 566 ; by the gas-oxygen-ethanesal and the gas-oxygen-chloroform-ethanesal combinations, 567 ; modern methods of, 1001 ; spinal, and its drawbacks (Dr. B. Desplas), 1233 ; (Prof. Dr. H. Finsterer) (R.), 1248 ; a surgeon's thoughts on, 1302
Anæsthesia, Practical Local (Dr. R. E. Farr) (R.), 889 ; Art of (Dr. P. J. Flagg), 3rd ed. (R.), 889
Anæsthetic, dental, for children, 141 ; from the surgeon's point of view, 301 ; sickness, treatment (Dr. J. Blomfield), 475 ; apparatus, improved, 938
Anæsthetics, acetylene and ethylene, 240
Anæsthetics, Handbook of (Dr. J. S. Ross), 2nd ed., 1923 (R.), 1248
Analytical Microscopy (Mr. T. E. Wallis) (R.), 20
Analytical Records (see Reports and Analytical Records)
Anatomy and Physiology, Text-book of (Dr. Elizabeth R. Bundy), 5th ed., 1923 (R.), 227 ; of the Human Form (Mr. U. W. A. Parkes) (R.), 937 ; Gray's, 22nd ed., 1923 (R.), 938
Anderson College of Medicine, opening address, 1001
Anderson, Dr. M. G., Obstetric Tables, 2nd ed., 1923 (R.), 937
Anderson, Mr. D., driving grip in golf, 154
Andrade, Prof. E. N. da C., Structure of Atom (R.), 1249
Andrews, Mr. J. A., modification of the Ringleb cystoscope, 1428
Aneurysm, arterio-venous, of neck (Mr. A. W. Mooro), 1186
Angina agranulocytolica, 1094
Angina pectoris, operations on cardiac nerves in (L.A.), 468 ; pectoris, prognosis in (Dr. J. Hay), 1119
Ankylostomiasis campaign in Madras, 1922, 475
Annual Charities Register and Digest, 1016
Anormale Kinder (Prof. L. Scholz), 3rd ed., 1922 (R.), 20
Ante-natal diagnosis (Dr. Frances M. Huxley), 321 ; care (Dr. R. A. Hendry), 548
Anthrax, origin and prevention of, 574
Antigen, defatted tubercle, 931, 955 ; pollen, prepared by Dreyer's method, 932
"Antimicrobum," Tomarkin's, 1310
Anwyl-Davies, Dr. T., and Dr. J. Mellanby, anticoagulating of arsenobenzols on blood, 555
Apex tracings, mechanical (Dr. A. Mougeot), 1182
Aphasia, dementia follows, 1254
Apnœa, inspiration, in a new-born infant (Dr. W. D. Kirkwood and Dr. B. Myers), 65
Apothecaries' Society of London, pass-lists, 43, 259, 487, 1012, 1279
Appendicitis, bilharzial, 28 ; caused by ascaris lumbricoides, 238
Appointments, weekly lists of, 49, 101, 152, 208, 263, 313, 368, 488, 538, 587, 633, 682, 815, 863, 910, 960, 1014, 1064, 1114, 1167, 1217, 1281, 1328, 1381, 1425
Approved societies and voluntary hospitals (Py Q), 100
Arey, Mr. L. B., twin tubal pregnancy, 27
Armstrong-Jones, Sir R., a correction, 1279
Army Medical Service (Py Q), 208 ; (see Students' Guide), 418
Aromatics and the Soul (Dr. D. McKenzie) (R.), 1086
Arsenical poisoning (work of Swedish Commission), 531
Arsenobenzols, anticoagulating action of on blood (Dr. T. Anwyl-Davies and Dr. J. Mellanby), 555
Arthritis, sulphur treatment, 80 ; chronic, treatment (Dr. W. H. Wynn), 617
Articulations, injuries and diseases of (Mr. A. G. T. Fisher), 541, 678
Ashby, Dr. H., after-results of abdominal tuberculosis in children, 362
Ashton, Mr. C. E., obituary, 1326
Ashworth, Prof. J. H., bearings of zoology on human welfare, 588
Aspiration, liver abscess treated by (Dr. A. R. Neligan), 1398
Association of Certificated Blind Masseurs, meeting, 60, 816
Asthma (Mr. F. Coke) (R.), 786
Asthma, treatment of (Dr. E. P. Poulton), 29 ; and protein idiosyncrasy and, 96 ; bronchial, due to mice, 131
Asylum superintendent's appointment (Py Q), 311
Atmospheric pollution, 577
Atom, new theory of (L.A.), 1041
Atomic Form (Mr. E. E. Price) (R.), 1086
Atomic physics, 616
Atoms (T. C. Wignall and G. D. Knox) (R.), 125 ; Studies of (Mr. B. Russell) (R.), 1249 ; Structure of (Prof. E. N. da C. Andrade) (R.), 1249
Avery, Dr. J. S., accidental vaccinia, 535
Augustus and Alice Waller Memorial, meeting, 1215

Australia, Correspondence from.—Government control of hospitals and charities ; Post-grad. teaching in Melbourne ; Hobart Hospital, Tasmania, 803—Insulin in Australia ; Australian Medical Congress, 804

Australia in the War of 1914–1918, Official History (Mr. H. S. Gullett and Mr. F. M. Cutlack) (R.), 835
Auto-pyo-therapy, 660
Ayurveda and Unani (L.A.), 659

B

Baby Week Conference, National, 33, 88
Bacillus coli infection, acute, of gastro-intestinal tract (Dr. R. C. Jewesbury and Prof. L. S. Dudgeon), 118, 874
Back, Mr. I., and Mr. L. Colledge, pharyngeal diverticulum, 1237
Bacteria digesting cellulose, 1198
Bacteriological Diagnosis (Von Dr. H. Schottmüller) (R.), 226 ; (Dr. L. Pincussen) (R.), 226

Bacteriology, Practical (Surg.-Gen. E. R. Stitt), 7th ed., 1923 (R.), 607 ; Practical, for Chemical Students (Prof. D. Ellis) (R.), 607
Bailey, Dr. C. H., and Dr. E. A. Bullard, bilharzial appendicitis, 28
Baitsell, Dr. G. A., Evolution of Man (R.), 170
Balfour, Dr. A., problems of acclimatisation, 84, 243 ; Wellcome Bureau of Scientific Research, a correction, 631 ; director of the new School of Hygiene, 992
Balkan remedies for disease, 816
Bamford, Mr. D. St. J., private wards in London hospitals, 1058
Bankart, Mr. A. S. B., treatment of flat-foot, 799
Barker, Dr. L. F., Clinical Diagnosis of Internal Diseases (R.), 71
Barlow, Sir T., the late Mr. H. D. Farnell, 858
Barnes, Dr. H. A., Tonsils, Faucial, Lingual and Pharyngeal (R.), 567
Barnes, Eleanor C. (Lady Yarrow), Alfred Yarrow, his Life and Work (R.), 22
Barykin, Prof. W., and Dr. N. Kritsch, infecting agent of exanthematic typhus, 78
Bashford, Dr. E. F., obituary, 536
Beaton, causation of mental disorder, 121
Beattie, Prof. J. M., action of particles of slate on toxins, 668
Beatty, Dr. J., psoriasis, 1139
Beatty, Dr. W., death of, 1106
Béchamp or Pasteur ? (E. D. Hume) (R.), 1084
Beck, Dr. J. C., Applied Pathology in Diseases of Nose, Throat, and Ear (R.), 1356
Bedside table, invalid's, 286
Bee honey, New Zealand imperial, 1036
Bee-sting on the uvula, 864
Beers, Mr. C. W., A Mind that Found Itself (R.), 1084
Beit Memorial Fellowship, 131
Belfast Royal Victoria Hospital, retirement of Prof. T. Sinclair, 99
Bell, Prof. B., use of lead in treatment of malignant disease, 1425
Bennett, Dr. R. A., Hodgkin's Disease (R.), 610
Beri-beri in Madras Presidency, 35
Berkeley, Mr. C., use and abuse of forceps, 560
Berkeley-Hill, Maj. O., Ranchi European Medical Hospital, India, 122

BERLIN, CORRESPONDENCE FROM.—Title of "specialist" ; Meeting of Socialist doctors, 138—Control of new drugs ; Conditions in the Rhenish spas, 139—Prophylaxis of measles, 476—Medical men and the Profiteering Act ; Threatened strike of club doctors ; Combating the red ant ; Insurance against hospital expenses ; Quality of milk in Berlin, 477—Supply of medical books ; Model Rontgen institute ; 478—Care of war victims ; Accidents due to drunkenness ; Height and weight in children ; Treatment of tuberculosis, 622—Case of pneumo-peritoneum ; Regulation of medical fees ; First-aid huts in Berlin, 803—Changes in the Workmen's Insurance Act ; Letters patent for Dr. Friedmann ; Help to the Ruhr children, 1319—Venereal clinics, 1320

Bernhard-Smith, Mr. A., Poisonous Plants of all Countries, 2nd ed., 1923 (R.), 609
Bertrand, Dr. E. N. da C., Structure of the Atom (R.), 1249
Bertwistle, Dr. A. P., the silhouette radiogram, 783
Bethlem Royal Hospital, course of lectures, 1380
Bezançon, F., and S. I. de Jong, Maladies de l'appareil respiratoire (R.), 1034
Bianchi, Prof. L., on old age, 343
Biggs, Mr. H., death of, 91
Bigland, Dr. A. D., pellagra in British islands, 1295
Bilharziasis in Dongola Province of Sudan, 942 ; of ureter (Aly Bey Ibrahim), 1184 ; prevention of, 1372
Biliary system, secondary operations upon (Sir B. Moynihan), 4
Bing, Dr. R., Kompendium der topischen Gehirn- und Rücken-marksdiagnostik (R.), 281
Biochemistry and medicine (L.A.), 791 ; (Dr. C. Oppenheimer), 2nd ed., 1923 (R.), 1194
Biological Technique (Prof. E. Abderhalden) (R.), 1305
Biomathematics (Dr. W. M. Feldman) (R.), 463
Birmo, Swiss natural bitter water, 570
Birth control information (Py Q), 261 ; control and Ministry of Health, 1428
Birth injuries, intracranial, 1292
Births, illegitimate (Py Q), 101
Births, marriages, and deaths, weekly lists of, 49, 102, 152, 208, 263, 314, 368, 438, 489, 538, 588, 634, 682, 815, 863, 911, 960, 1015, 1064, 1115, 1168, 1217, 1281, 1328, 1381, 1425
Bismuthyl, bi-quinyl, and injectable urenile, 1358
"Black Jack" signature books, 1150
Blackham, Col. R. J., cows' milk in infant feeding, 361 ; correction, 859
Blacklock, Dr. B., ætiology of kala-azar and tropical sore, 273
Blackwater fever, ætiology of, 1362
Bladder, diverticulum of (L.A.), 467, 935 ; "idiopathic," hypertrophy of, 1191
Blair, Dr. Mary A., prophylactic treatment of puerperal sepsis, 95
Blake, Mr. F., case of exomphalos, 976
Blepharitis and styes (Dr. R. A. Greeves), 997
Blind, home care of, 92 ; welfare of, 660
Bliss, Dr. O., chronic tonsillitis and puerperal sepsis, 1363
Blomfield, Dr. J., anæsthetic sickness, 474
Blood and Blood Diseases (Von Dr. Med. O. Naegeli) (R.), 520 ; Sugar in Man, Investigations on (Dr. K. M. Hansen) (R.), 980 ; Grouping (Prof. L. Lattes) (R.), 1142 ; Pressure, High (Dr. J. F. H. Dally) (R.), 1250
Blood-fat and blood-sugar, inter-relationship of (Dr. T. H. Oliver and Dr. A. Haworth), 114 ; sugar, effect of bacterial extracts on, 370 ; donors, 585 ; pressure in new-born, 614 ; pressure, high (Dr. E. M. Brockbank), 880, 883 ; pressure in scarlet fever, 941
Bloxam, Mr. A. G., and Dr. S. J. Lewis, Bloxam's Chemistry, Inorganic and Organic, 11th ed., 1923 (R.), 1086
Board of Control, annual report, 662 ; for Scotland, report, 942
Boas, Dr. E. P., cardio-vascular complications of kyphoscoliosis, 471
Body, the wisdom of (Prof. E. H. Starling), 865
Boenheim, Dr. F., thymus extract as a therapeutic agent, 291
Boileau, Dr. Margaret, obituary, 679
Bonar, Dr. T. G. D., mastoid disease, 1079
Bone, carpal, semilunar, curious condition of, 943 ; marrow after splenectomy, 1254 ; necrosis after avulsion of scalp, 1310
Bones and Joints, Inflammation of (Dr. L. W. Ely) (R.), 334
Bonney, Mr. V., and Dr. H. M. McCrea, gynæcology and general medicine, 1025
Bose, Sir J. G., Life Movements in Plants (R.), 788 ; circulation and assimilation in plants, 1331
Bourne, Mr. A. W., acute salpingitis, 559
Bovinine, a raw food extract, 1144
Bowel, large, diseases of, 887
Bower, Prof. F. O., immobility of plant-body, 1220
Bowman, Dr. A. K., syphilis as a complication of tuberculosis, 1288
Box, Dr. C. R., London Fever Hospital, 1111
Boycott, Prof. A. E., action of alcohol on man, 1055
Boyle, Dr. H. E. G., anæsthesia by gas-oxygen-ethanesal and gas-oxygen-chloroform-ethanesal combinations, 567
Boyle, Mr. R., Ventilation of Public Buildings (R.), 282
B.P. codex, the new, 79
Bradbury, Dr. F. C. S., estimating urea in urine, 1246
Braeuning, Dr., is reinfection of tuberculosis from within or without ? 130
Branson, Dr. W. P. S., life assurance and syphilis, 472
Breast, Diseases of (Mr. W. H. Evans) (R.), 787
Breast, hypertrophy of (Mr. D. C. L. Fitzwilliams), 218 ; pump, hygienic, 636
Brighton and Sussex Med. Chir. Society (see Med. Socs.).
Brighton water-supply, 1215
Bristow, Mr. W. R., and Mr. C. M. Page, Fractures in General Practice (R.), 1355
British Association at Liverpool, 470 ; scientific exhibits, 616 ; atomic physics, 616 ; symbiosis in animals and plants, 668 ; diet and cancer, 668 ; action of particles of slate on toxins, 668 ; measurement of colour-blindness, 668 ; insulin and its value in medicine, 668 ; anthropology, 669
British Dental Association, annual meeting at Manchester, 294
British Jour. of Anæsthesia, 471
British Jour. of Experimental Biology, 615

BRITISH MEDICAL ASSOCIATION (Annua Meeting at Portsmouth).—(L.A.), 177—Public health policy, 185—Hospital policy, 188—Scientific work ; Medical Women's Federation ; Public health matters ; National Health Insurance, 189—Financial statement ; State recognition of opticians, 229—Notification of convictions to G.M.C., 230—Overseas branches ; non-panel practitioners ; notification of venereal disease, 231—Annual dinner, 232, 988
Section of Medicine.—Diabetes, 354—Heart disease in early life, 355—Chronic bronchitis, 357. *Surgery :* Obstruction of colon, 295—Operative treatment of malignant disease ; acute primary infections of hand, 298—Ventriculography, 300—Anæsthetics from the surgeon's point of view, 301. *Public Health :* Recent decrease in infant mortality, 302—Value of watercress ; sewer air, 303—Coal gas and ill-health, 304. *Laryngology and Otology :* Internal ear deafness, 358—Retrobulbar neuritis of nasal origin ; surgical treatment of nasal deformity ; spasm of larynx ; organotherapy in ear, nose, and throat work, 359. *Diseases of Children :* Acidosis and alkalosis, 360—Cow's milk in infant feeding ; summer diarrhœa, 361—After-results of abdominal tuberculosis, 362. *Neurology and Psychological Medicine :* Nervous child, 457—Sequelæ of encephalitis lethargica, 459—Prognosis of psychoses during adolescence, 461. *Tuberculosis : Artificial light treatment*, 511—Surgical treatment, 512—Social aspects, 513. *Ophthalmology :* Clinical significance of scotometry, 515—Ophthalmology and Navy, Army, and Air Force, 516. *Obstetrics and Gynæcology :* Acute salpingitis, 559—Use and abuse of forceps, 560. *Radiology and Electrology :* X ray examination of urinary tract, 562—Medical diathermy, 563. *Venereal Diseases :* Chronic gonorrhœal prostatitis and vesiculitis, 565. *Anæsthetics :* Anæsthesia for children, 566—Fatalities from anæsthetics ; anæsthesia by the gas-oxygen-ethanesal and the gas-oxygen-chloroform-ethanesal combinations, 567. *Exhibition :* Surgical instruments and appliances, 304—Drugs and pharmaceutical appliances, 305—Food preparations, 362—Medicinal and mineral waters ; microscopes and scientific apparatus ; sundries ; medical agencies ; books and office accessories, 363

British surgeons in Denmark, 804
Broadhurst, Dr. J., How We Resist Disease (R.), 20
Brockbank, Dr. E. M., high blood pressure, 880, 883 ; Heart Disease, 5th ed., 1923 (R.), 982
Bronchitis, chronic, 357
Bronchomoniliasis (Dr. Th. Jockes and Dr. R. H. Simpson), 109
Brook Fever Hospital (Py Q), 149
Brown, Dr. F. W. C., thermal death-point of tubercle bacillus in milk, 317
Brown, Dr. W. L., Sympathetic Nervous System in Disease, 2nd ed., 1923 (R.), 125
Browne, Dr. F. J., induction of labour by quinine and pituitrin, 1401
Browne, Sir J. W., death of, 1424
Browne's (Sir Thomas) skull, 616
Brugsch, Prof. T., and Prof. A. Schittenhelm, Klinisch Laboratoriumstechnik (R.), 936
Brühl, Prof. Dr. G., Lehrbuch und Atlas der Ohrenheilkunde (R.), 981
Bubonic plague in Great Britain, rôle of pulex irritans in, 292
Buckley, Dr. C. W., diuresis, 1300

BUDAPEST, CORRESPONDENCE FROM.—Terminal hæmaturia ; Neosalvarsan in chorea ; Death of an eminent ship's surgeon ; Wheat currency ; Census figures ; Child Welfare Exhibition, 253—Numbers of the medical profession in Hungary ; Scientific and Commonwealth Universities, 802—Unjustified accusation, 803—Insurance against sickness in Hungary ; Sick and crippled children, 1106—Pre-matriculation examinations in the universities, 1208—Excessive taxation of medical men; Doctors and the telephone, 1209

Bugs (Dr. E. A. Butler) (R.), 519
Bull, a prehistoric, 1170
Bull, Prof. P., surgical treatment of pulmonary tuberculosis, 1239
Bullough, Dr. W. A., problems of health service in rural districts, 1116
Bundy, Dr. Elizabeth R., Text-book of Anatomy and Physiology, 5th ed., 1923 (R.), 227
Burford, Dr. G., Cancer (R.), 1084
Burgess, Mr. N., and others, insulin in diabetes mellitus, 777
Burgess, Prof. A. H., obstruction of colon, 295; X rays in exophthalmic goitre, 364
Burke, Dr. E. T., chronic prostatitis and lupus erythematosus, 1187
Burleigh, Mr. H. W., private wards in London hospitals, 1111
Burma Corporation, medical and sanitary work with (Dr. J. P. Cullen), 1426
Burrell, Dr. L. S. T., improved aspirator, 790
Burrows, Mr. H., physical and recreational training, 309; Abdominal Surgery for Nurses, 2nd ed., 1923 (R.), 1086; temperature of skin over lipomata, 1347
Burton, Dr. A. H. G., Milne treatment of scarlet fever, 679
Bust, portrait, unidentified, 907
Butler, Dr. E. A., Biology of the British Hemiptera-Heteroptera (R.), 519
Buzzard, Dr. E. F., sequelæ of encephalitis lethargica, 459; traumatic neurasthenia, 1285

C

Cæsarean section, symphysiotomy, and craniotomy (Mr. A. E. Chisholm), 276
Cairo School of Medicine, work at, 1253
Calculus, renal, bilateral (Mr. C. Noon),325
Caledonian Medical Society, meeting, 44
Calendars and diaries for 1924, 1428
Calf lymph, supplies of (Py Q), 1164
Calmette, Albert, Tubercle Bacillus Infection and Tuberculosis in Man and Animals (R.), 281
Cambridge University, pass-lists, 98, 908, 957, 1423; additional annual grant for pensions, stipends, &c., 813
Cambridgeshire, Tuberculosis Colony, 995
Cameron, Dr. H. C., the Nervous Child, 2nd ed., 1923 (R.), 72; the nervous child, 457; intracranial birth injuries, 1292
Cameron Prize lecture, the story of insulin, 952
Cammidge, Dr. P. J., is diabetes mellitus a progressive disease? 40; acidosis and alkalosis in children, 360
Camphor, intravenous injection of, 1200
Canadian Social Hygiene Council, report, 1112
Cancer Congress at Strasbourg, 801; research, prize for, 1214; and oral sepsis (L.A.), 1307; of œsophagus, radiotherapy in, 1318; cure, a new, 1384
Cancer, deaths from (Py Q), 46; pitch (Py Q), 48; mortality (Py Q), 48; resistance to the induction of (Dr. J. A. Murray), 159; facts and cancer theories (L.A.), 177, 308; areas (Py Q), 261; and diet (L.A.), 612, 668, 675, 798, 858
Cancer, memorandum of Departmental Committee of Ministry of Health, 479
Cancer Research Fund, Imperial, annual report, 135, 1368; research campaign and the cancer problem, 308, 365, 484; (L.A.), 1359; research in Manchester, 367, 487; operations, mammary, results of, 1057
Cancer, Theories and Problems of (Prof. C. E. Walker) (R.), 73; Fallacy, Theory, and Fact (Dr. J. Shaw) (R.), 568; Cancer (Dr. G. Burford) (R.), 1084
Candy, Dr. T. I., X ray diagnosis of pregnancy, its medico-legal aspect, 955
Cannon, Dr. W. B., Traumatic Shock (R.), 888

CENTENARY OF THE LANCET.

Special Supplement, pp. 687 to 764.

Foreword, 685—Synopsis, 686—List of Illustrations, 686.

Founding of The Lancet.—Medical training in 1823, 687—A mysterious outrage; The first medical weekly, 688

The First Ten Years.—A fierce struggle; Copyright in lectures, the Abernethy case, 691—Malpraxis in hospitals, Bransby Cooper case, 693

A Fight with Authority.—Constitution of the Royal College of Surgeons, 695—Agitation, constitutional and otherwise, 697

Medicine and the Public.—Appeal to public interests, 698—Advocacy of medical coroners; Food Adulteration; Anatomical study, body-snatching and murder, 699

Medicine in Parliament. — Thomas Wakley as public man; Thomas Wakley, M.P., 701—Germ of medical registration, 702 — Warburton's famous committee, 703—First Medical Reform Bill, 705

Eighty Years Ago.—Early clinical communications; Entente with France, 707—Cholera epidemic of 1831, 709

Popular Journalism.—Illustrated biographies, 710—" Intercepted letters," 711—Illustrated biographies, second series, 712

The Lancet in the 'Fifties.—A critical period, 714—Organised movement against tuberculosis, 715—Treatment of insanity, 716; Conduct of lunatic asylums, 716—Analytical Sanitary Commission, 717—Influences of railway travelling, 721

The Second Editor, 723—Workhouse administration, Anstie's work, 724—James Wakley's staff; Four well-known collaborators, 726

Continuity and Progression.—The Lancet and the Royal corporations, 727—Anæsthetics, 728—The fight against bacteria, 732—The distinction between pathogenic and non-pathogenic bacteria: asepsis, 735

Public Affairs and Medical Journalism.—Disrespect for personages, 736—Staunton case, 738—Metropolitan Hospital Sunday Fund, 739—Epsom College, 740—Medical Act of 1886, 741

The Lancet in the 'Eighties. — Clinical work; The co-editorship, 742—Thomas Henry Wakley, 743—Some loyal friends, 745—Registration of midwives, 747—The Lancet commissions, 748—Brighton drainage, 749

The Last Thirty Years.—Staff of The Lancet, 749—Collaborators in 1893; More old friends, 750—The Infectious Diseases Notification Act, 752—The Mirror of Hospital Practice, 753—Doom of the unqualified assistant, 754—Battle of the Clubs, 755—Some generalities; An unpleasant experience, 756—The printing department; The third Thomas Wakley, 757

Close of the Centennium.—Change of ownership, 758—National Insurance Act, 759—Inquiries into public matters, 760—The war; Experiments in nutrition, 761—Belgian Doctors' and Pharmacists' Relief Fund, 762—French Supplement to The Lancet; Ministry of Health, 763—S. A. Vasey, 764

Centenary of The Lancet Dinner (speeches and list of visitors), 1267

Congratulatory messages to The Lancet on its Centenary, 807, 856, 905, 955, 1007, 1055, 1209

Founder of The Lancet, a personal reminiscence (Dr. M. Grabham), 1006

Cerebral conditions, hypertonic and hypotonic saline solutions in, 1191
Cerebro-spinal Fluid in Health and Disease (Dr. A. Levinson) (R.), 226
Chadburn, Dr., diseases of the large bowel, 887
Chalmers, Dr. R., acute *B. coli* infection of gastro-intestinal tract, 874
Chalmers, Sir M. D., London Fever Hospital, 1162
Chamberlain, Dr. W. W., obituary, 307
Chambers, Surg. Rear-Admiral J., new Director-General of Naval Medical Service, 179
Chambers's Encyclopædia (Mr. D. Patrick and Mr. W. Geddie) (R.), 788
Chaney, Dr. W. C., splenic anæmia, 290
Chappel, Dr. G. P., obituary, 1377
Charities, medical, 307
Chaslin, Dr. P. A., death of, 1318
Chauvois, Dr., Les désanglés du ventre; Maladies par relâchement des parois et organes abdominaux (R.), 170
Cheatle, Mr. A. H., alcohol injections for neuralgia, 1407
Cheese, milk, and cream standards (Py Q), 149
Chelsea Clinical Society (see Med. Socs.)
Chemistry, Bloxham's, Inorganic and Organic (Mr. A. G. Bloxham and Dr. S. J. Lewis), 11th ed., 1923 (R.), 1086; Systematic Organic (W. M. Cumming and others) (R.), 1403; (Dr. C. Oppenheimer) (R.), 1404
Chest signs, mistaken, 344
Chicken-pox and small-pox, differential diagnosis, 40; (Py Q), 101; 485; unusual case (Dr. H. C. Pattin), 510
Childbirth, deaths of women in (Py Q), 311
Child mortality (Py Q), 151; adoption (Py Q), 151; mortality in Scotland (L.A.), 178
Child, the difficult, 1033; the nervous, 1242
Childe, Mr. C. P., environment and health, 155
Children employed in mines (Py Q), 260; defective, to parents of, 370; height and weight of, in Germany, 622
Children's Country Holidays Fund, 51; Sanatorium at Holt, 80
Child's death in hospital (Py Q), 311
Chisholm, Mr. A. E., symphysiotomy, craniotomy, and Cæsarean section, 276
Cholera in Bombay, 1276
Chorea, neosalvarsan in, 353; passive hyperæmia in, 525
Choyce, Mr. C. C., System of Surgery, 2nd ed. (R.), 786
Civil service officers, reduction of bonus, 537
Clare, Dr. T. C., gastromyotomy, 602
Clark, Dr. A. J., commercial influences in therapeutics, 1067
Clarke, Dr. A. V., R.M.B. Fund, 257
Clarke, Mr. J. J., a national pathological museum, 484
Clausen, Dr. R. J., improved anæsthetic apparatus, 938
Clearkin, Dr. J. M., anaphylactic shock, 1080
Clements, Dr. J. H., panel practitioner's right of appeal, 95
Climatology, limitations of available information on, 1097
Climatology, Medical, in England and Wales (Dr. E. Hawkins) (R.), 1356
Climber, the trained, 154
Coal gas in causing ill-health, 304
Cocaine traffic and long sentences, 247; substitutes, comparative value of, 1297
Code words for medical telegrams, 367
Cœliac disease (Dr. R. Miller), 1099

Coffey, Dr. R. C., Gastro-Enteroptosis (R.), 888
Coffin, Dr. S., dental anæsthetic for children, 141
Cohen, Dr. H., hypertonic and hypotonic saline solutions in cerebral conditions, 1191
Coke, Mr. F., Asthma (R.), 786
Colbeck, Dr. E. H., and Dr. S. R. Gloyne, Spahlinger's vaccine in tuberculosis, 116
Colebrook, Dr. L., and Dr. E. J. Storer, immuno-transfusion, 1341, 1394
Coleman, Mr. G. S., Calculations in Heating and Ventilation (R.), 282
Colitis, chronic (Dr. A. Abrahams), 1411
Colledge, Mr. L., and Mr. I. Back, pharyngeal diverticulum, 1237
Colles's fracture (Dr. H. Platt), 1201
Collie, Sir J., pitfalls of medico-legal practice, 1136

Royal Academy of Medicine in Ireland.—Election of officers, 902—*Section of Pathology.*—Tubal pregnancy; Intrathoracic sarcoma, 1083

Royal Medico-Chirurgical Society of Glasgow.—Disseminated sclerosis, 1033

Royal Society of Medicine.—Comparative value of cocaine substitutes, 1297; Chronic abdominal pain in nervous women, 1347—*Section of Anæsthetics.*—Condensation of dimethyl ether and its use as an anæsthetic, 1301—A surgeon's thoughts on anæsthesia, 1302. *Balneology and Climatology.*—Diuresis, 1300. *Dermatology.*—Syphilis of nervous system, 932. *Medicine and Surgery.*—Surgical treatment of pulmonary tuberculosis, 1239. *Medicine, Comparative.*—Integration of medicine, 977—Cryptorchidism in animals and man, 978. *Ophthalmology.*—Cases and specimens, 1135—Interstitial keratitis, 1136. *Orthopædics.*—Myositis ossificans traumatica (cases), 1350. *Otology.*—Changes in the inner ear in a deaf boy; Otoliths in fishes; Cases, 1031. *Pathology.*—Ætiology of malignant disease and leukæmic phenomenon; Defatted tubercle antigen, 931—Pollen antigen prepared by Dreyer's method, 932—*Evolution* and disease, 1241—Meaning of fever, 1242. *Study of Disease in Children.*—Cases and specimens, 978, 1190. *Surgery.*—Surgery of the hepatic and common bile-ducts, 15. *Therapeutics and Pharmacology.*—Insulin in general practice, 885. *War.*—Gonorrhœa, 1134

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—*Maternity and Child Welfare Group.*—Feeding of infants between the ages of 1 and 5 years, 69

ULSTER MEDICAL SOCIETY.—Insulin in diabetes mellitus, 1192—Unilateral diuresis; Estimating urea in urine, 1246

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—Cases, 887—Tabes dorsalis, 1139

Medical Society for Study of Venereal Diseases (see Med. Socs.)
Medical Society of London, Fothergillian medal and prize awarded to Sir A. Keith; (see also Med. Socs.)
Medical Women's Federation, meeting, 1013

MEDICINE AND THE LAW.—House-letting and infection, Collins *v.* Hopkins, 34—Liability for impure water-supply; Authority to engage an ambulance, 89—Cocaine traffic and long sentences; Bedrid criminal; Libel on a medical referee; Interpretation of skiagrams, 247—Unjust censure; Poor persons, the law, and medicine; Tests of intoxication, 1053—Criminal acts and mental deficiency; Indecent exhibition closed, 1206; A judge upon evidence of insanity, 1317

Medicine and surgery in Ireland (Sir W. I. de C. Wheeler), 1169
Medicine, History of (Sir D'Arcy Power) (R.), 125; Modern, Autobiographical Studies in (Prof. L. R. Grote) (R.), 126; Debt of, to the Fine Arts (Dr. J. A. Nixon) (R.), 464; Social (Dr. P. Trisca) (R.), 519; Series, Practical (Dr. G. H. Weaver and others) (R.), 1034; Pathological, Précis of (F. Bezançon and S. I. de Jong) (R.), 1034; Legal, and Toxicology (Dr. F. Peterson and others), 2nd ed., 1923 (R.), 1248
Medicine in industry, 249; scholarship in (Sir H. Morris), 314; the outlook in (L.A., Student's Guide), 415; scholarship in, 484; in India, indigenous systems of (report of Madras Committee), 669; and dentistry, hopeful outlook, 839; integration of, 977; and literature (L.A.), 1146; modern, in Iceland, 1309; radio-activity in (Prof. S. Russ), 1314; in Holland (L.A.), 1361
Medico-legal practice, pitfalls of, 1136
Medico-Psychological Association, Dr. M. J. Nolan elected President, 313; (see also Med. Socs.)
Melæna neonatorum, 1366
Mellanby, Dr. J., and Dr. T. Anwyl-Davies, anticoagulating action of arsenobenzols on blood, 555
Meller, Dr. J., Ophthalmic Surgery, 3rd ed., 1923 (R.), 1193
Meningitis due to worms, 895
Menorrhagia in young women without gross lesion (Dr. J. S. Fairbairn), 578
Mental cases, early, treatment in general hospitals (wards at Middlesex Hospital), 32; deficiency administration (Py Q), 46; patients, welfare of, 103; disorder, effects of intercurrent maladies on (Dr. E. Goodall), 107; tests for delinquents (Dr. M. H. Smith and Dr. G. W. Pailthorpe), 112; disorder, early treatment (Dr. J. G. P. Phillips), 120, 871; disorders and chronic sepsis, 121; disorder, psychogenic factor in, 121; disorders, basal metabolism in, 122; hospitals, dysenteric infection in, 122; disease, research in (L.A.), 127
Mental hospitals, visiting committees in (Py Q), 151; hospitals, a standard for, 661; hospitals, plea for their nationalisation, 676; defectives, Worcestershire home for, 1016; inefficient, "treatment" or "punishment," 1044; After-care Association, need of funds, 1425
Mental Hospitals Service, 74, 140, 143, 255, 534, 583, 1037, 1090, 1157, 1321, 1420
Mentally deficient, care of (L.A.), 657
Metabolism, Inborn Errors of (Prof. A. E. Garrod), 2nd ed., 1923 (R.), 464
Metastatic gonorrhœa, 18
Metropolitan Asylums Board, courses, 259
Michie, Dr. H., obituary, 957
Middlesex Hospital conversazione, 1381
Middleton, Dr. E. L., dust inhalation and pulmonary disease, 470
Midwifery teaching and practice in India, 1219
Midwifery, Text-book of (Dr. R. W. Johnstone), 4th ed., 1923 (R.), 836
Midwives, training of, 577; and maternity nurses, practising, a directory of, 1016
Milk, pasteurised (Py Q), 100; vans, dirty (Py Q), 149; dried, regulations for labelling, 205, 1097; feeding experiments (Py Q), 207; tubercle bacillus in, thermal death-point of (Dr. F. W. C. Brown), 317; Pasteurisation of (report by the Ministry of Health), 338; clean, production of, 346; quality of, in Berlin, 477; dried, standardised, 1093
Milk (Special Designations) Amendment Order (Scotland), 1923, 367; pasteurised (L.A), 521; Condensed, Regulations, 793; cans, silent, 962; Conference, National, discussion on pasteurisation, 1205
Milks, skimmed dried (Py Q), 100; condensed, bacteriology of (report to Food Investigation Board), 529
Military preparedness, medical, 1407
"Military Surgeon" and its editor, 1094
Miller, Dr. H. C., the nervous child, 1242
Miller, Dr. R., heart disease in early life, 355; cœliac disease, 1099
Milner, Dr. A. E., and Dr. K. Maclachlan, diathermy treatment of gonorrhœa in women, 652
Milroy, Dr. J., insulin in diabetes mellitus, 1192
Milroy lecturer for 1925, applications invited for, 1256
Mind, the Unconscious (Dr. S. Herbert) (R.), 1034; That Found Itself (Mr. C. W. Beers) (R.), 1084; in Action (G. H. Green) (R.), 1249
Miners' nystagmus (Py Q), 263; compensation, 292; (L.A.), 1092; psychoneurotic symptoms in, 1110
Mingazzini, Prof. G., Eine Anatomische, Physiopathologische, und Klinische Studie (R.), 21
Minister of Health's offer (L.A.), 1039
Ministry of Health rate, 46
"Mintite" hot-water bottle, 590, 1328
Miosis, congenital, 614, 906

MODERN TECHNIQUE IN TREATMENT: (27) Asthma (Dr. E. P. Poulton), 29—(28) Traumatic rupture of the urethra (Mr. G. G. Turner), 82—(29) Habitual constipation (Dr. A. F. Hurst), 134—(30) Hypertrophied prostate (Dr. C. A. Pannett), 184—(31) Infantile eczema (Dr. H. MacCormac), 242—(32) Exophthalmic goitre and other forms of hyperthyroidism (Dr. G. R. Murray), 293—(33) Syphilis in the woman of child-bearing age (Dr. Margaret Rorke), 348—(34) Anæsthetic sickness (Dr. J. Blomfield), 474—(35) Enuresis (Dr. H. Thursfield), 528—(36) Menorrhagia in young women without gross lesion (Dr. J. S. Fairbairn), 578—(37) Chronic arthritis (Dr. W. H. Wynn), 617—(38) Glycosuria in pregnancy (Dr. G. Graham), 663—(39) Flat-foot (Mr. A. S. B. Bankart), 799—(40) Duodenal ulcer (Dr. J. A. Ryle), 843—(41) Retention of urine (Mr. J. S. Joly), 896—(42) Treatment of the neurotic (Dr. S. A. K. Wilson), 945—(43) Blepharitis and styes (Dr. R. A. Greeves), 997—(44) Internal derangement of knee-joint (Mr. R. C. Elmslie), 1046—(45) Cœliac disease (Dr. R. Miller), 1099—(46) Treatment of varicose veins (Mr. P. Turner), 1152—(47) Treatment of Colles's fracture (Mr. H. Platt), 1201—(48) Pyelitis (Sir J. Thomson-Walker), 1257—(49) Prolapse (Mr. B. Whitehouse), 1313—(50) Epistaxis (Mr. J. G. French), 1367—(51) Chronic colitis (Dr. A. Abrahams), 1411

PRINTED BY HAZELL WATSON & VINEY LD., 52, Long Acre, W.C. 2, and PUBLISHED by the PROPRIETORS, WAKLEY & SON (1912), LTD., at No. 423, Strand, and No. 1, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, in the County of London

A Lecture

ON THE DIAGNOSIS AND TREATMENT OF CEREBRAL SYPHILIS.

A Post-Graduate Lecture for the Fellowship of Medicine, delivered at the Royal Society of Medicine

By GEORGE RIDDOCH, M.D. Aberd., M.R.C.P. Lond.,

FIRST ASSISTANT, MEDICAL UNIT, LONDON HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

This subject was chosen for discussion because, first, in the evolution of cerebral syphilis, widely different clinical pictures may be presented, giving rise to many difficulties in diagnosis, and, secondly, the disease can frequently be eradicated without leaving serious permanent disabilities if treatment is begun at an early stage and is sufficiently persistent. In cerebral syphilis the *Spirochæta pallida* has attacked mainly the meninges and blood-vessels. The neural tissues, however, rarely escape either direct invasion by the organism or local necrosis secondary to interference with blood supply; but encephalitis is superficial as compared with the deep and extensive process in dementia paralytica; hence the difference of the response to treatment. The pathological process may be limited throughout the course of the complaint to the intracranial contents, but usually the spinal cord, its roots or meninges are sooner or later also attacked.

HISTORY OF INFECTION AND DEVELOPMENT OF THE DISORDER.

When dealing with nervous disorders it is a commonplace to mention the importance of inquiry as a routine into the patient's previous history in regard to venereal infections. In men the history of chancre with or without a subsequent rash or sore-throat is obtained in a large proportion of cases of cerebral syphilis. Sometimes gonorrhœa but not syphilis is admitted, and later the Wassermann reaction is found to be positive. This important fact should be remembered, for there is no doubt but that an unobtrusive chancre may run its course unnoticed when the local reaction to gonococcal invasion is severe. In women this part of the investigation is more difficult, for it is, of course, as a rule undesirable to ask direct questions on this subject; but even when this is done a negative history of primary or secondary lesions is usually obtained. If the woman is married an inquiry into the results of her pregnancies should never be omitted.

Symptoms of cerebral syphilis may appear within a few months or even weeks of the infection or may be delayed for years. The development of the disorder as revealed by the history of the patient's symptoms is of great diagnostic importance. No symptom of which he may complain is peculiar to cerebral syphilis, nor can the grouping of symptoms and signs at any phase in the malady be made the basis of a confident diagnosis. But when the patient relates a story in which, for example, paroxysmal severe headaches, attacks of giddiness, transient cranial-nerve palsies, or mental deterioration are prominent, and the clinical examination reveals signs of multiple cerebral lesions, there is presumptive evidence of cerebral syphilis. The diagnosis is more certain if he admits syphilitic infection, and is complete if the specific serological tests are found to be positive.

Common characteristics of cerebral syphilis might be categorically stated as follows: (1) Multiplicity of symptoms pointing to organic lesions; (2) their frequent transient nature; (3) the consequent changefulness of the clinical picture presented at different stages in the evolution of the disorder. These features, however, may be said to be equally characteristic of two other diseases of the central nervous system—namely, disseminated sclerosis and encephalitis lethargica. We will deal with their differential diagnosis as occasion arises.

COMMON CLINICAL MANIFESTATIONS IN CEREBRAL SYPHILIS.

It would be unprofitable in a single lecture to attempt to describe fully the symptomatology of cerebral syphilis in relation to diagnosis. Our time will be better spent if we confine our attention to the more common clinical forms of the disorder and to deal with diagnostic difficulties under each symptom-group.

Headache, Vomiting, and Giddiness.

One of the almost constant early symptoms is headache. It is usually severe and may be described as throbbing and stabbing, and, at its height, often stupefying in its intensity. Although paroxysmal, each attack usually lasts for hours and may persist for days on end. The pain may be worst in some region of the head, but it is most commonly general and often associated with tenderness of the scalp as a whole. When the pain is circumscribed—for example, in the frontal, temporal, or occipital region—and is accompanied by a fan-shaped area of cutaneous tenderness spreading upward, it is generally due to involvement of the corresponding cutaneous nerves in a gumma of the skull or its coverings. Between the paroxysms the pain may disappear, but more commonly a dull ache persists. Too much has been made of nocturnal aggravation of the syphilitic headache. During attacks of severe pain the patient is frequently giddy and may vomit repeatedly, and sometimes he is found on examination to have either optic neuritis or papillœdema. The occurrence of these symptoms with or without other clinical manifestations raises the question of cerebral tumour. When cranial-nerve palsies are present without pupillary abnormalities the differential diagnosis between tumour of the basal membranes and syphilitic basilar meningitis often depends entirely on the results of examination of the blood and spinal fluid.

Cranial-Nerve Palsies.

Very few cases of syphilitic meningo-encephalitis run their course without involvement of one or more cranial nerves and, with affection of the basilar membranes, they tend to be attacked early. The palsies that result from these lesions are frequently transient, and throughout the course of an illness signs of damage to several cranial nerves may appear at one time or another and leave little or no permanent disability. Any cranial nerve may be attacked, but some are more commonly injured than others. Disorders of smell are not rare, and limitation of the visual fields on one or other side may be an early sign from invasion of the optic nerves, chiasma, or tracts. Papillœdema when present is usually bilateral, but optic neuritis may occur on one side only. Unilateral deafness is very common and may be associated with weakness of the facial muscles on the same side and pain and tenderness of the skin in the distribution of one or more divisions of the fifth nerve. But pupillary abnormalities, such as a fixed dilated pupil, ptosis, diplopia, or squint from lesions of the third or sixth cranial nerves, are most common of all. The fourth nerve is less often affected. These oculomotor signs may be unilateral or bilateral and are often evanescent.

Of disorders of the pupil the Argyll Robertson phenomenon is the most diagnostic, but in regard to it a word of warning is necessary. First, it is less frequently found in cerebral syphilis than in tabes and dementia paralytica, and its absence should not necessarily be taken as evidence against a diagnosis of syphilitic infection. Secondly, although this sign is most often a manifestation of neurosyphilis it is not pathognomonic of it. It signifies a lesion in a particular part of the mid-brain which, though usually syphilitic, is occasionally due to some other cause. For example, it sometimes occurs with tumour in this region, or with encephalitis lethargica. Thirdly, defective reaction of the pupils to light is as significant as complete absence of response. For example, the movement may be small, sluggish, or delayed and, in spite of continuous stimulation, contraction may be immediately followed by dilatation or to-and-fro movements of the pupil may go on. The diagnostic value of these latter abnormalities is enhanced if they are unilateral. Irregularity in outline or eccentricity of the pupil may also be met with.

Transient cranial-nerve palsies are as common in disseminated sclerosis as in cerebral syphilis, but pupillary changes and severe paroxysmal headaches are very rare in the former, and nystagmus is rare in the latter. When physical signs are present elsewhere they may aid the diagnosis, but many are common to the early stages of both conditions. Manifestations of root lesions, such as local atrophies, or pain and tenderness of radicular distribution, would strongly favour a diagnosis of syphilis. Often differentiation between the two disorders on clinical grounds only is extremely difficult, and must rest on serological tests.

Changes in pupillary reactions are common in encephalitis lethargica, but defective reactions on accommodation or convergence are perhaps most frequently found, although the Argyll Robertson phenomenon sometimes occurs. When in this disorder alterations in the reactions of the pupils are present, they are usually accompanied by lethargy or insomnia, a combination of symptoms which is by no means unknown in cerebral syphilis. Mild pyrexia may also occur in both, so that on clinical grounds only it is sometimes impossible to make a diagnosis. In such circumstances, examination of the blood and spinal fluid is of the greatest value.

MENTAL CHANGES.

Because of the striking nature of the mental alterations in dementia paralytica they have become well recognised. But clinicians are less generally familiar with the psychological abnormalities that are to be found almost constantly in subjects of cerebral lues during some phase or other of their illness, and may be the most prominent feature of the clinical picture presented. This hiatus in general medical knowledge of the disorder may be in part ascribed to the varied character of these mental changes, and also to their close resemblance to some neuroses and psychoses. Thus, in milder cases, the symptoms complained of may at first sight be indistinguishable from those of neurasthenia. The patient is listless, depressed, tearful, worried over trifles, has great difficulty in paying sufficient attention to his business, and in being interested in affairs that used to engross his attention: his memory for recent events is faulty and his diminished efficiency is a source of great worry to him. The resemblance of this disordered mental state to neurasthenia is enhanced by its changefulness in that periods of spontaneous improvement occur.

By careful attention to the nature of certain symptoms, however, points of distinction can often be made out. For example, the neurasthenic headache is more a discomfort than a pain. It is often described as a sensation of weight on the top of the head or of pressure in the temples, or as if a band were constricting the head. On the other hand, the characteristic headache in cerebral lues is severe, prolonged, and prostrating and may be associated with repeated vomiting. Again, the syphilitic looks more ill, is more tremulous, and his fears are less liable to be temporarily dissolved by robust optimism and reassurance. But although these distinctions may excite suspicion, the diagnosis really rests upon the results of careful inquiry into the mode of onset and development of the illness, the question of venereal infection, and examination of the patient for physical signs. If the diagnosis is still in doubt, the reactions of the blood and spinal fluid should be investigated. It should, of course, be remembered that neurasthenic symptoms in a patient who has been infected with syphilis does not necessarily mean that they are manifestations of meningo-encephalitis or arteritis. Although the infection may have been effectively treated at an early stage the patient may doubt the completeness of the cure and dread a recrudescence of the complaint in some terrible form. Under such circumstances a neurosis may readily germinate and develop in a sensitive individual. Suicides from this cause are not unknown. Many syphilophobics have had syphilis, but not all have been cured of their infection, and in every case thorough investigation is an essential preliminary to diagnosis and treatment.

Not uncommonly in cerebral syphilis more severe grades of mental derangement are met with. The neurasthenia-like state we have been considering may be interrupted by a phase of delirium or maniacal excitement, and if the patient is first seen in one of these attacks the diagnosis of the underlying cause may be very difficult. In the delirium there may be complete disorientation with visual hallucinations, but, unlike the hallucinations in delirium tremens, these do not usually take the form of loathsome animals and horrible faces. The absence of evidence of peripheral neuritis and the presence of Argyll Robertson pupils and other suggestive signs aid the diagnosis. An accurate account of the patient's previous health and of his habits would, of course, be of great help, but this is not always easy to obtain from relatives and attendants.

Sometimes periods of excitement alternate with periods of semi-consciousness in which purposive actions, such as ordinary household duties, may be carried out without any memory of them being retained.

An interesting mental disorder in relation to diagnosis is one in which there is an uncontrollable desire to sleep lasting for days, often succeeded by insomnia. When prolonged lethargy of this kind is an early symptom, encephalitis lethargica would naturally be suspected. As already mentioned, diplopia and defective reactions of the pupils, to light or on accommodation or both, are common in this disease and are another source of confusion. Often the diagnosis must rest on serological tests. A lymphocytosis in the cerebro-spinal fluid may be found in encephalitis lethargica as well as in cerebral syphilis, but in the former the Wassermann reaction (W.R.) in both blood and spinal fluid is negative.

Any of the mental disturbances we have so far considered may pass into dementia, and although it is denied by some observers, there is no doubt but that intellectual and emotional impairment may gradually develop as the sole manifestation of disordered mental function in cerebral syphilis. The following excellent example is at present under my care in the London Hospital.

A man of 43 contracted syphilis in 1903 in South Africa. He had held a good position and had average ability. In 1912, while acting as assistant purser on board ship, he had a seizure, after which he was aphasic and paralysed on his right side. He lay in a stuporose state for three or four days, refusing food, and passing urine and fæces under him. Some time later in the same year he was admitted to the London Hospital under the care of Dr. Henry Head; in the hospital records it is stated that he was dull and apathetic and lay curled up in bed, speaking only when he was questioned. He gave sensible answers to simple questions, but his memory even for past events was very poor and his attention feeble. He was completely disorientated in regard to time and was unable to give correctly his age or dates of occurrence of prominent events in his life. He did not suffer from headache, but vomited occasionally and had incontinence of urine and fæces. Careful examination of his nervous system failed to reveal any other abnormalities, except tremulousness of his hands. The W.R. in his blood was strongly positive but negative in his spinal fluid, which contained only two cells per cubic millimetre.

Between May, 1912, and October, 1913, he was given a course of mercurial inunctions and two injections of salvarsan;

he improved considerably, but remained mildly demented, leading an idle existence, apparently without interest in anything. Until recently he has been living on a farm, but unless someone was continually with him to spur him on, he could not direct his attention or stimulate his interest even for a short time to carry out simple duties. He is not at all resistive, but is apathetic and listless and has no desire to do anything. His memory is still very defective, and he is as disorientated as he was before. There is a very slight weakness on voluntary movement of his face and tongue and palate on the right side, and although his pupils react well to light the contraction is not maintained. The W.R. in the blood is still positive, but the spinal fluid is normal.

This case is of interest for several reasons: (1) It is a good example of simple dementia due to meningo-encephalitis; (2) onset after an apoplectiform seizure is not uncommon in such cases; (3) few physical signs are present; (4) the improvement up to a point with antisyphilitic treatment; (5) the non-progressive character of the disability during the last ten years; and (6) absence of changes in the spinal fluid.

I have enlarged upon this case also in order to stress the fact that dementia in a syphilitic subject does not necessarily mean general paralysis of the insane. The distinction is important, for dementia paralytica is invariably fatal within a few years of its onset, and treatment is of little or no avail in arresting its progress. Further, I am convinced that as the result of wrong diagnosis many cases of meningo-encephalitis with dementia are sent to asylums as incurable, and in consequence are not treated. In *dementia* paralytica remissions and relapses occur, but its course is progressive, leading to increasing mental and physical deterioration; the W.R. is probably always positive, not only in the blood but also in the cerebro-spinal fluid, which in addition shows an increased globulin content, lymphocytosis, and the so-called paretic form of colloidal gold curve.

Before leaving the subject of dementia as a manifestation of cerebral syphilis, another diagnostic difficulty must be mentioned. When the disorder appears in adolescence it may easily be confused with dementia præcox. The resemblance is increased if negativism is present, as it may be. But a careful inquiry into the evolution of the illness, together with a search for signs pointing to focal cerebral lesions and investigation of the reactions of the blood and spinal fluid, will clear the diagnosis.

Hemiplegia.

It is, I am sure, unnecessary to remind you that hemiplegia, occurring in a patient under middle age who is not a subject of cardiac disease, is very frequently due to cerebral syphilis. Strictly speaking, it is perhaps most frequently a manifestation not of meningo-encephalitis but of arterial disease, and although the W.R. is positive in the blood it is commonly negative in the cerebro-spinal fluid. When, however, it is accompanied by changes in the pupils, cranial-nerve palsies, or evidence of spinal-root lesions the spinal fluid usually shows specific alterations.

Epilepsy.

Jacksonian attacks are well-recognised symptoms of meningo-encephalitis of the convexity of the brain, and I need not do more than mention them in passing. But I wish to draw attention to the undoubted occurrence in cerebral syphilis of recurring seizures, often indistinguishable from those of idiopathic epilepsy. This clinical form of the disease is not common, but along with cerebral tumour it should be kept in mind when a patient over 20 develops epileptic seizures for the first time. They may be of either the grand mal or petit mal variety and usually recur at fairly long intervals. A feature of them which may help in diagnosis is that the patient is often dazed or stuporose or a longer time after the attack than is usual in diopathic epilepsy. Pupillary abnormalities or other organic signs, when present, would suggest the possibility of syphilis as the underlying cause and the W.R. ought to be examined. It is needless to say, however, that a positive W.R. in an epileptic does not necessarily prove that syphilis is at the base of the complaint; but if physical signs are present and antisyphilitic treatment has a beneficial effect it is practically certain that the syphilitic infection is the cause.

VALUE OF LABORATORY TESTS IN DIAGNOSIS OF CEREBRAL SYPHILIS.

Discussion has recently been renewed in regard to the diagnostic value of the W.R. in syphilitic infections. In relation to diseases met with in this country, with a few known exceptions, it can confidently be said that a definitely positive reaction indicates infection with syphilis, when the test is performed by a competent clinical pathologist. A negative result, however, is not always of the some clear value in diagnosis. For example, in tabes a negative reaction in the blood is by no means uncommon during a quiescent phase; even in the spinal fluid the reaction is sometimes found to be negative.

In cerebral syphilis when the disease is progressive a positive W.R. in the blood can almost always be obtained. In the cerebro-spinal fluid the reaction may be positive or negative. It may be negative when the disease is confined to the cerebral arteries, or sometimes—as in the case of the dementia I have quoted—even when the pathological process is more extensive but the contents of the spinal canal have escaped. A positive W.R. in the spinal fluid is practically always accompanied by lymphocytosis, increased globulin content, and a positive colloidal gold curve.

TREATMENT.

When cerebral lues is diagnosed early, and suitable treatment instituted, good results in a large number of cases can be expected. The disease can frequently be eradicated, and failing this ideal result improvement almost always takes place. But to attain this end treatment by antisyphilitic remedies must be carried out for a long time, and, equally important, it should be judicious. To get the maximum beneficial effect the physician should never lose sight of the patient's general health in his eager attack upon the disease. The drugs used are, in large doses, highly poisonous, and idiosyncrasies to them are not rare.

In severe cases of cerebral syphilis, when the patient is in poor health or when his mental functions are seriously disordered, he should, during treatment, be confined to bed until his condition improves. His diet must be supervised, and when somnolent he may have to be artificially fed.

Insomnia and restlessness or maniacal excitement can best be treated by warm baths and hypnotics, such as paraldehyde or veronal. A useful drug for this purpose is morphine bimeconate in a 2 per cent. aqueous solution. It is given by the mouth in water, an average dose being 25 or 30 minims, repeated in two or three hours if necessary. It has a most soothing effect, especially in cases of nocturnal restlessness. Severe headaches may be the cause of sleeplessness, and when so the treatment of insomnia lies in giving relief from pain. In such circumstances the following powders will be found useful. The basis of them is 5 gr. each of aspirin and pyramidon. If this fails to give relief, one-twelfth or one-sixth grain of heroin hydrochloride should be added. This will usually be successful; but if the patient, although free from pain, is still unable to sleep, the addition of 2½ or 3 gr. of veronal will be sufficient in most cases to give the desired result.

For epileptic seizures sedatives as well as antisyphilitic drugs are necessary. In my experience a combination of bromide and luminal-sodium is best. An average dose is luminal-sodium gr. i., sodii brom. gr. v. with liq. arsenicalis ♏ ii., and inf. gent. co. ½ oz.

twice or thrice daily; but the dose must be suitably adjusted in each individual case. A localised gumma of the meninges on the convexity may have to be removed by operation, if it is giving rise to progressive symptoms of cerebral tumour which antisyphilitic treatment fails to relieve. There is no absolute contra-indication to the use of antisyphilitic remedies, but for old and feeble patients, especially when the kidneys are diseased, small doses should be used and a close watch kept on renal function.

Of the drugs at our disposal arsenobenzol compounds, mercury, and potassium iodide are the most important. Novarsenobillon is the arsenical preparation most used in this country, in doses of 0·15 to 0·9. In my opinion, as a single dose 0·6 g. should rarely be exceeded, and in order to ascertain the patient's tolerance to the drug it is wise to begin with small doses. The drug can be given intravenously, subcutaneously, or intramuscularly. If the subcutaneous or the intramuscular method is employed the drug must be dissolved in aqueous glucose or an oily medium. Sicard, who advocates these methods, uses novarsenobenzol, galyl, or sulpharsenol in small doses—0·15 to 0·2 g., repeated every two days for two months. The injections are said to be almost painless, and excellent results are claimed for this form of treatment.

The method I usually adopt is to give four or six weekly injections of novarsenobillon. This is followed by a course of three or four weeks' duration of mercury either in the form of inunctions or by mouth, together with potassium iodide. An interval of three or more weeks, according to the condition of the patient, is now allowed to elapse before treatment is again begun. The effect of treatment should be gauged at the end of each complete course, not only by the clinical condition of the patient, but also by the reactions of his blood and cerebro-spinal fluid; for it must always be remembered that the disappearance of the patient's symptoms does not necessarily mean that his disease has been cured.

Treatment should be continued periodically, even after improvement in the laboratory tests and in the clinical state has ceased. In general, after two to four complete courses of novarsenobillon, mercury, and potassium iodide, further treatment should be delayed for from 6 to 12 weeks. The necessary precautions during treatment with mercury and potassium iodide and the symptoms of poisoning by these drugs are well known and need not detain us now. But the dangers associated with the administration of arsenic may be mentioned. In the first place, patients with an idiosyncrasy to the drug are now and again met with, hence the advisability of testing as a routine the tolerance to organic arsenic by the administration of an initial minimum dose. When there is an unusual susceptibility to the drug the patient, within a few minutes of the injection, may be seized with malaise, vomiting, and pyrexia, and an erythematous rash may appear. Secondly, sometimes a more intense and even fatal reaction of the nature of anaphylactic shock is met with. On the day after the first or a subsequent injection of novarsenobillon convulsions, pulmonary œdema, and coma may rapidly develop and the patient may die. Thirdly, a few hours after an injection the patient's symptoms may be temporarily increased—the so-called Herxheimer reaction. The appearance of one or other of these reactions is a contra-indication to either further use of arsenic or, if it is continued, the employment of more than minimum doses. Lastly, prolonged and injudicious administration of arsenic will lead to chronic poisoning, of which early symptoms are erythematous eruptions, jaundice, and peripheral neuritis. Arsenic therapy must then be discontinued for at least two or three months.

In closing, let me again insist that either disappearance of symptoms or a stationary clinical state is not by itself a reliable indication of cure of the disease. But in general the syphilitic infection has been eradicated when in addition the specific tests in the blood and spinal fluid have remained negative for five years.

SECONDARY OPERATIONS UPON THE BILIARY SYSTEM.[1]

By Sir BERKELEY MOYNIHAN, Bart.,
K.C.M.G., C.B., F.R.C.S. Eng.,
SENIOR SURGEON, LEEDS GENERAL INFIRMARY; PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF LEEDS.

The subject allotted to me in this discussion concerns those cases in which a recurrence of symptoms takes place after an operation upon the common bile-duct. About one-fifth of the total number of patients suffering from cholelithiasis upon whom I operate have previously been submitted to operation for this condition. Secondary, tertiary, or multiple operations upon the biliary system may be made necessary by a variety of causes, among which the chief are the nature and condition of this disease, and of its complications and remote effects; and imperfect primary operations.

Factors in Stone Formation.

A study of the nature and condition of the disease must chiefly have regard to the factors bringing about the formation of stone. These factors are dual: infection reaching the bile channels, and an increase in the cholesterol content of the blood. The great majority of the stones which require removal are formed in the gall-bladder; when stones are found in the ducts it is because they, or the small particles from which the larger stones develop, have escaped from the gall-bladder. But there are cases, happily few in number, in which stones are formed in the smaller ducts within the liver, or in the larger ducts which lead to the intestine. An infection may reach the gall-bladder from several directions—from the blood-stream; from the bile flowing downwards from the liver; from the lymphatic plexuses of the appendix, pancreas, liver, &c., which most freely anastomose with that of the gall-bladder; from the common duct, which in turn receives infection from the duodenum; and finally, by contiguity through adhesions to neighbouring organs. Though these are the direct and proximal routes, it is evident that the infection travelling along them is not necessarily a primary infection in the organ from which it is immediately derived. Infection coming from the liver may be primary elsewhere in the body, gain access to the blood-stream, mature in the spleen, and ultimately reach the liver by way of the splenic vein. A search for infective lesions must therefore involve a scrutiny of the whole body, so that the most lurking area of infection may be revealed. A failure to discover such an infection may be responsible for a recurrence of stones in the gall-bladder, the liver, or its ducts.

The cholesterol content of the blood is an important agency in the causation of gall-stones. We have still a good deal to learn with regard to cholesterin, and its presence in the blood in excess in certain conditions. Blood cholesterol determinations have been made for me by Miss Shiskin on a large number of patients suffering from various abdominal disorders, and 100 consecutive cases have been scrutinised for the purpose of this review. In conditions other than cholelithiasis or cholecystitis, low or normal values have been found to be the rule. In uncomplicated cases of cholelithiasis, on the other hand, the cholesterol content of the blood tends to be high. Thus in 40 such cases examined the blood cholesterol values ranged from 0·133 per cent. to 0·409 per cent., the average value being 0·210 per cent. If we take 0·160 per cent. as the average normal figure, with 0·192 per cent. and 0·133 per cent. as the upper and lower normal limits, 60 per cent. of the cases are seen to be hypercholesterolæmic, and, although in the remaining 40 per cent. the cholesterol content of the blood is normal, it is to be noted that in three-quarters of these (that is 30 per cent. of the total) high normal values have been obtained.

---

[1] The opening remarks made at a discussion on the Surgery of the Hepatic and Common Bile-ducts at the Royal Society of Medicine on June 27th, 1923.

In all the cases of cholelithiasis examined a marked fall in the cholesterol content of the blood was observed shortly after the operation. This fall is not confined to cases of cholelithiasis. It has been noted by me in diverse other conditions after major surgical procedures, for example, after prostatectomy, gastrectomy, splenectomy, &c. In the cases under discussion the fall is to be attributed sometimes to the direct drainage of the biliary passages, but the effects of the anæsthesia, the slight elevation of temperature sometimes present after an operation, and, indeed, the disturbed metabolism consequent on operation, must all be regarded as contributing factors. Subsequent re-examinations show that after the initial fall there is a rise, in some cases, a progressive one, so that the cholesterol content of the blood may soon reach the pre-operative figure. Such cases belong to the diathetic group; that is to say, they are more or less continuously hypercholesterolæmic, and even after operation for cholelithiasis the hypercholesterolæmia may persist. In the majority of the patients, however, the cholesterol content of the blood had fallen to normal and was found to have remained at the normal level when examined 14 months after the operation.

The treatment of the patient after operation must therefore take into account this condition of hypercholesterolæmia. The following instructions as to diet are given to all patients after operation:—Articles of diet which must be avoided: Yolk of egg, brains, kidneys, sweetbreads, liver, goose and duck, pork and game, fat, stewed and fried meats, cream and cheese, fresh fruit and green vegetables (for three months), butter (only to be taken in small amounts, if at all). A recurrence of symptoms after an operation upon the common bile-duct may also depend upon the following circumstances.

Imperfect Primary Operations.

1. Stones may be overlooked or left behind in any part of the extrahepatic ducts, including the ampulla of Vater. There are times when even a practised surgeon may have his doubts about the presence of a stone in the common duct. In cases when the gall-bladder is thick and shrivelled, and has ceased to perform its functions, the common duct may be found not a little dilated. After the gall-bladder has been removed the same change constantly occurs. What Rutherford Morison calls the "natural cure" of cholelithiasis consists in the closure of the cystic duct and the shrinking of the gall-bladder until it becomes a mere fibrous or calcareous covering for the stones remaining inert within its cavity. The common duct then may be obviously, even grossly, dilated. The question of how best to decide whether such a duct contains a stone is one that surgeons answer differently. The enlargement of glands along the duct and the presence of hard nodules in the head of the pancreas may cause the surgeon to feel almost confident that a stone is present. And in such circumstances the opinion is very generally given that the duct should always be opened and "explored." I disagree most confidently. Exploration of the duct with anything but the finger is a most uncertain method of discovering or locating a stone. A probe or a small scoop will miss a calculus, even one of good size, over and over again, especially if it happens to be in a little pocket aside from the main channel of the duct. Beyond any question the surest method of deciding whether the duct contains a stone is to pass the first and second fingers of the left hand through the foramen of Winslow and the thumb in front of it, and to palpate the duct and compress it between the fingers and thumb, as they travel gently upwards and downwards. To the expert fingers the tiniest fragment of stone can be felt as soon as the duct is empty of bile. The left hand of an assistant, if he too is expert, should carry out an independent investigation. During the last few years I have rarely opened a common duct merely for the purpose of deciding whether it contained a stone. The exploration of a sufficiently dilated duct can be carried out with the left forefinger passed inside it with the extreme probability that with adequate skill and unwearied patience the last fragment of stone will be discovered.

When a stone which lies concealed in the ampulla of Vater has been overlooked at the primary operation, the duodenum *should be opened and McBurney's or* Kocher's operation performed. After either of these operations the drainage of bile into the duodenum is very free and unimpeded. I am very fond of both of these methods. They can be performed with the utmost daintiness and precision, with extremely little risk, and with the confident prospect of a perfect result. The making of a large opening at the lower end of a dilated duct, with, or more often without, the suture of the duct edges to the duodenal wall, will allow stones of even medium size to escape readily into the intestine. I feel sure that these operations are not practised sufficiently often. I am beginning to entertain a belief that they may be the safest of all operations upon the *common* duct, and those in which there is the most confident prospect of complete relief for the future. At least I can claim that their range should be greatly extended. Even when it is not necessary to open the duodenum the dilatation of the lower part of the duct *from above is a most useful* procedure. It may be effected by the passage of probes of the type suggested by Mayo, or by the passage of a rubber catheter through the duct into the duodenum. A later reference will be made to this procedure.

2. Particles of grit may be left in the lower intrahepatic ducts, or in the hepatic or common duct, and inadequate drainage may not give them time to escape. The question of drainage after the operation of choledochotomy is one that still exercises the minds of surgeons, and certain surgeons who ought to know better are practising and advocating the immediate suture of the duct after every operation upon it. In every case of obstruction of the common duct by calculus there is cholangitis, and in a large number of cases there is mud, or dust, or sand, in addition to the larger stones. When there is a large solitary stone of recent descent from the gall-bladder, the closure of the duct may sometimes be safely performed. I have done this a few times in years gone by, always with a feeling of anxiety during the few days following operation, and with no ultimate advantage of any kind to the patient. I make it a rule, and have done for many years, to drain the hepatic duct in all cases of multiple stones. Some of the patients are gravely ill, and in them the method of McArthur of passing a catheter down the duct into the duodenum for the purpose of giving fluid nourishment is invaluable. The catheter acts by the method of "continuous dilatation," which Sir Henry Thompson originated and wisely advocated for the treatment of urethral stricture. Any narrowing of the common duct is, for a time at least, completely overcome, and during that time the smaller stones or the coarse dust and mud of the ducts above are able to escape into the intestine. I give through this tube a 5 to 15 per cent. solution of glucose, with a little carbonate of soda, by the "drip" method, interrupting the steady flow every three or *four hours, to give a meal of peptonised milk*, beaten eggs, &c. As much as 10 to 12 pints of fluid a day may be introduced in this way with great advantage. The tube remains for ten days to a fortnight.

When many stones and much mud have been removed from the common and hepatic ducts, small particles of grit may long continue to descend upon the gauze strips passed up into the ducts to clear them. In such cases I pass Carrel tubes up into as many of the intra-hepatic ducts as I can recognise. These ducts are sometimes so large as easily to contain the finger, and there is no difficulty in passing tubes into them. Around the common-duct incision a barrier of dental rubber is placed. At the end of 24 to 36 hours, when the peritoneal cavity is sealed off, I start the intermittent irrigation by the method of Carrel, washing the ducts out with large quantities of sterile salt solution or plain boiled water. In one such case the nurse counted a few hundred stones and weighed them, and finally weighed the total mass of tiny stones and particles of coarse dust washed down from the liver. She assessed their total number in this way, as "well over a million"! The operation was four years ago, and there has been no recurrence of symptoms, though the operation I performed was the fourth attack made on the common duct. For the first ten days an abundance of fluid was given through a catheter passed into the duodenum. This case raised the question as to the origin of the infection responsible for the formation of the stones. It would appear that in such cases the most likely route of delivery of infective material to the liver is by the splenic vein. In a later case than this, where the spleen was slightly enlarged, I performed the sixth operation upon a patient, drained the blocked hepatic ducts of many thousands of small stones, and then removed the spleen. The washing out of the ducts continued for six months; after that time the bile drained away through the wound, which has closed and broken down again several times since, but stone formation appears definitely to have ceased. I therefore advocate drainage of the hepatic duct in all cases of multiple calculi; drainage with irrigation of the ducts in many of the cases, especially the secondary ones, in which the ducts contain great quantities of mud, the employment of the method of McArthur of catheterism of the lower part of the duct; and in cases in which the lowest part of the duct contains calculi, a more frequent resort to the operation of McBurney. If typhoid organisms are found in the bile the administration of urotropine by the "thump" method is necessary. Thirty grains of acid sodium phosphate in one pint of water are taken during the day, and at night a single dose of urotropine beginning at 30 and increasing to 60 gr. is taken. At the end of a week a respite of a few days is allowed during which alkalies are given. The administration of urotropine again begins and is again interrupted.

3. In cases of primary cholecystectomy failure to divide the cystic duct at the proper place may be responsible for disaster. The variations in the mode of entry of the cystic duct into the common duct and of the variations in the vascular supply of the gall-bladder and ducts have not been sufficiently considered by surgeons in the past; the recent work of E. R. Flint in this connexion may be studied with great advantage. The cystic duct not infrequently runs for an inch or more side by side with the common hepatic duct, to which it is closely bound, until it enters with it into the formation of the common duct. The two may, indeed, not unite until they almost reach the duodenum. If a long piece of the cystic duct is left behind a stone may lie within it and there ncrease, or may quietly migrate from it and escape nto the common duct. On the other hand, too much of the cystic duct may be removed, and with it a piece of the common duct, or of the hepatic duct. The pelvis of the gall-bladder is at times so intimately adherent to the common duct that when the gall-bladder is lifted up to enable the cystic duct to be cleared, the common duct may be stretched, and then o closely resemble the cystic duct that the greatest care is necessary to distinguish them. The inviolable ule in the surgery of the gall-bladder and of the ommon duct is this: "See exactly what you are doing, and until you see do nothing." On four occasions I have removed a part of the common hepatic or common bile-ducts, happily not to a degree prejudicing the recovery of the patient, because mmediate repair of the duct was performed. If this ragedy should occur it should be redeemed at once. The parts are then all in view, and supple, and estoration is not by any means as difficult as it will rove to be in later weeks or months. It is the surgeon who bungles in this fashion who is then the only ufferer. He feels that the operation has not displayed hat degree of ease and mastery in efficient action which stamp the artist; and he has the misery of knowng that he has given less than his best to his patient. If too much of the cystic duct is removed, and with a part of the common duct, a stricture of the latter may result. This stricture may itself be responsible for symptoms which closely resemble those of a floating stone, or be the means of causing that degree of stagnation of bile which leads to infection and makes easier the formation of a stone. A few cases have come my way in which a complete segment of the common duct had been excised, and I have had to reconstruct the duct or to anastomose the hepatic duct to the duodenum.

Improper Operations.

At the primary operation upon a case of cholelithiasis when stones are present both in the gall-bladder and in the common duct, the question as to the best procedure to adopt with reference to the gall-bladder will always arise. At a time when operations were performed with difficulty and attended by grave risk, at a time, too, when relief from symptoms after operations by competent surgeons was less frequent than it is now, it was felt that removal of the gall-bladder was unwise. If mistakes were to be made at all, it was safer to make the mistake of leaving the gall-bladder than the mistake of removing it; the former error could be made good, the latter was almost irreparable. But as the quality of surgery improved, and as by degrees we learnt that recurrence of stones in the common duct was so frequently due to recurrence first taking place in a gall-bladder which had only been drained, and that pancreatitis might arise and often probably did arise by extension from the walls of a diseased gall-bladder, the practice of the removal of the gall-bladder grew more common. A study of its walls showed often that they were filled with organisms, and that the elastic and muscular coats were so thoroughly disorganised, and the mucosa so changed, as to render the viscus incapable of adequately fulfilling its functions either as a reservoir competent to discharge its contents on demand, as a regulator of the rate of discharge of bile, or as an organ secreting a constituent which it was proper for the bile to possess on entry into the intestine or otherwise. The cases in which the gall-bladder is needed for anastomosis with the duodenum at a second operation are now so exceedingly few that this consideration need hardly weigh with the surgeon as he reflects upon the course he is to follow.

The present practice of most surgeons whose experience is large is to remove the gall-bladder at the time the common duct is emptied of its stones.

Involvement of the Pancreas.

There are conditions of the pancreas, its chronic or subacute inflammatory states, that may cause a very close mimicry of the symptoms of calculous obstruction of the common duct. The frequency of the association of disease of the pancreas with cholelithiasis is variously estimated by different observers. The pancreatic changes are not easily measured during an operation. It is difficult to gauge the size of an organ so long and so remote with any approach to accuracy; and qualities of texture in respect of hardness, in one part or another, cannot be expressed in terms that make one surgeon's experience comparable with that of another. Removal of a portion of the pancreas is open to the fallacy that the area chosen may not be equally involved with the rest of the organ. But with all due and necessary allowance for these truths there can be no doubt of the frequency, and the occasional grave severity, of the pancreatic changes. The route by which infection reaches the pancreas is not necessarily the same in all cases. The cause of the cholelithiasis may be the cause of the pancreatitis, or the latter may be the consequence of the former. If the pancreatitis is secondary to cholecystitis the infection may travel from the gall-bladder down the common duct, and along the canal of Wirsung; or it may pass in the lymphatic plexus which is common to the two. Some clinical and all experimental evidence (especially Nordmann's) suggests that invasion by the ducts is the more likely; but there is evidence, too, derived from operations, that lymphangitis may be the chief factor in causing the changes in the pancreas. Whichever may be, in any special case, the correct explanation, it is evidently a safer plan to remove the gall-bladder than to drain it. Cholecystectomy is beginning to displace cholecystenterostomy in the treatment of chronic pancreatitis, as a result, chiefly, of the advocacy and practice of Deaver.

The typical symptoms of calculous obstruction of the duct may occur in the absence of calculus. In operating upon such cases it is a little disconcerting to find a distended common duct in which no stone is present. The head of the pancreas, especially, will be found enlarged and hard and œdematous. The duct lies in such intimate relationship with the gland, that a swelling of the latter compresses the duct, causes stagnation of bile, and consecutively a degree of cholangitis that may be very severe. In such cases the T-shaped tube of Kehr may be used to drain the hepatic duct intermittently, or, as I prefer, two catheters may be introduced, one draining the hepatic duct, the other passing downwards into the duodenum and affording the channel by which abundant nourishment may be given.

Operations on Deeply Jaundiced Patients.

All the operations upon deeply jaundiced patients raise two questions—that of hepatic insufficiency and of its avoidance, if such be possible, by an adequate preliminary preparation of the patient, and that of post-operative hæmorrhage. The symptoms due to the failure of the liver are apt to come quite unexpectedly. The operation has perhaps presented no unusual difficulties, and the patient leaves the operation theatre in good condition. For a few days all goes well; then one of two events attract serious attention. The amount of bile discharged may suddenly diminish or almost cease; jaundice deepens slowly; the pulse becomes slower; the mind is clouded; nourishment is sparsely taken or refused, when it is well taken vomiting begins; the amount of urea in the blood steadily augments, the patient grows rapidly weaker, and dies after a period of coma. In these cases, as Walters has shown, it is renal failure consecutive to hepatic failure that causes death. Or the picture so well described by Walters and Parham may be seen.[2]

"*Clinical Picture of Hepatic Insufficiency.*—Usually the first two to eight days after operation the course is uneventful; biliary drainage and urinary output are normal, fluids are taken well, the pulse and temperature are normal. One of the first signs of the onset of trouble is paling and thinning of the bile with marked increase in the flow. This profuse cholerrhagia does not continue long, but the bile remains thin. The patient begins to grow weaker, the pulse loses volume, and the temperature becomes subnormal. Restlessness and irritability develop with great fatigue and muscular weakness. Soon regurgitant vomiting follows intake of liquids by mouth and little taken by rectum is retained. Jaundice does not deepen markedly, but there is an increasing pallor beneath the icteric blue, the face becomes drawn, and the eyes anxious. The patient grows progressively weaker and finally dies. The urinary output remains proportional to the fluid intake throughout, and the urine reveals little or no evidence of marked nephritis. The blood-urea remains persistently low."

Post-operative hæmorrhage is due to the reduced power of coagulation of the blood, and this probably depends upon a lack of calcium salts. The deficiency of these is made good in two ways, by direct transfusion of blood, or by the intravenous administration of 5 c.cm. of a 10 per cent. solution of calcium chloride on three successive days, as advised by Walters, and by Lee and Vincent. The giving of calcium salts by the mouth even in colloid form has little effect, when, indeed, it has any, upon the calcium content of the blood. The coagulation time of the blood may be brought down to the normal or to the near neighbourhood of the normal by the intravenous administration, and the operation carried out at the appropriate moment. In all these cases it is necessary to administer as much glucose as possible by the mouth and by the rectum, and at the operation to take every care to ligature the smallest vessels. It may sometimes be prudent to postpone the removal of the gall-bladder because of the slow but unceasing weeping of blood from the denuded surface of the liver which sometimes follows upon cholecystectomy.

Secondary operations upon the biliary system are among the most difficult tasks in surgery. To obtain the best results all the highest qualities of the surgeon may be called into play: courage, resource, patience, accuracy and rapidity of judgment, the finest craftsmanship, and a tranquillity of mind and action that nothing can disturb.

STONE IN THE COMMON AND HEPATIC DUCTS.

BY JAMES SHERREN, C.B.E., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL, ETC.

THE presence of stones in the common and hepatic ducts is usually significant of the absence of efficient treatment in the particular patient in whom they are found. They denote failure in carrying out the only satisfactory treatment of gall-bladder disease, early cholecystectomy; this would have effectually prevented their entrance into the ducts. This failure is due to errors in diagnosis as well as inefficient treatment. Patients are still too often treated for various types of dyspepsia; that is, symptoms only are treated, and even after the onset of colic we still see attempts made to avoid operation. There is no medical treatment known at present that will remove the cause of the stone formation or dissolve those already formed; all attempts at such must fail and the ultimate death-rate far exceeds that of the curative surgical procedure. The relative number of cases operated upon at the stage when this complication has arisen must vary somewhat in every district according to the skill and bias of its practitioners and the skill and reputation of its surgeons. The percentage in Sir Berkeley Moynihan's private patients as given at Leeds last year was 21·96 (67 out of 305), differs little from mine, 18·5, which includes both hospital and private cases (113 out of 600).

It is obvious from my opening remarks that I do not believe stones form primarily in the ducts except certain rare pigment calculi associated with disease elsewhere. They may, however, increase in size and in number when infection is present and extend in a continuous column from the ampulla of Vater to the liver and even fill the intra-hepatic ducts. It follows, therefore, that if stones are found in the *common duct* after a previous operation for gall-stones, they must have re-formed in the gall-bladder, if this was left, or have been overlooked. This is easy unless they are systematically searched for, and even then they may be missed.

Difficulty of Pre-Operative Diagnosis.

Pre-operative diagnosis is only possible in the presence of typical attacks of colic associated with jaundice, often with rise of temperature. Jaundice is usually present at some time during the progress of the case; thus, in the 113 patients upon whom these remarks are based it had occurred in 78, but only in 33 was it severe and present at the time of operation. Many stones may be present in the common duct without producing jaundice and, on the *other hand*, a transient jaundice may follow an attack of biliary colic and the ducts are found at operation to be clear and the correctness of this confirmed by the subsequent history. In most instances the patient was operated upon for gall-bladder disease and the stones found in the ducts, not by accident but as a result of a definite exploration. Among the 33 cases in whom marked jaundice was present at the time of operation, in 2 it had never been associated with pain; as a distended gall-bladder could be felt the diagnosis of carcinoma of head of pancreas was arrived at. In the majority there was a history of abdominal symptoms extending them, and finally weighed the total mass of tiny stones and particles of coarse dust washed down from the liver. She assessed their total number in this way, as "well over a million"! The operation was four years ago, and there has been no recurrence of symptoms, though the operation I performed was the fourth attack made on the common duct. For the first ten days an abundance of fluid was given through a catheter passed into the duodenum. This case raised the question as to the origin of the infection responsible for the formation of the stones. It would appear that in such cases the most likely route of delivery of infective material to the liver is by the splenic vein. In a later case than this, where the spleen was slightly enlarged, I performed the sixth operation upon a patient, drained the blocked hepatic ducts of many thousands of small stones, and then removed the spleen. The washing out of the ducts continued for six months; after that time the bile drained away through the wound, which has closed and broken down again several times since, but stone formation appears definitely to have ceased. I therefore advocate drainage of the hepatic duct in all cases of multiple calculi; drainage with irrigation of the ducts in many of the cases, especially the secondary ones, in which the ducts contain great quantities of mud, the employment of the method of McArthur of catheterism of the lower part of the duct; and in cases in which the lowest part of the duct contains calculi, a more frequent resort to the operation of McBurney. If typhoid organisms are found in the bile the administration of urotropine by the "thump" method is necessary. Thirty grains of acid sodium phosphate in one pint of water are taken during the day, and at night a single dose of urotropine beginning at 30 and increasing to 60 gr. is taken. At the end of a week a respite of a few days is allowed during which alkalies are given. The administration of urotropine again begins and is again interrupted.

[*] A contribution to a discussion on the Surgery of the Hepatic and Common Bile-ducts at the Royal Society of Medicine on June 27th, 1923.

3. In cases of primary cholecystectomy failure to divide the cystic duct at the proper place may be responsible for disaster. The variations in the mode of entry of the cystic duct into the common duct and of the variations in the vascular supply of the gall-bladder and ducts have not been sufficiently considered by surgeons in the past; the recent work of E. R. Flint in this connexion may be studied with great advantage. The cystic duct not infrequently runs for an inch or more side by side with the common hepatic duct, to which it is closely bound, until it enters with it into the formation of the common duct. The two may, indeed, not unite until they almost reach the duodenum. If a long piece of the cystic duct is left behind a stone may lie within it and there increase, or may quietly migrate from it and escape into the common duct. On the other hand, too much of the cystic duct may be removed, and with it a piece of the common duct, or of the hepatic duct. The pelvis of the gall-bladder is at times so intimately adherent to the common duct that when the gall-bladder is lifted up to enable the cystic duct to be cleared, the common duct may be stretched, and then so closely resemble the cystic duct that the greatest care is necessary to distinguish them. The inviolable rule in the surgery of the gall-bladder and of the common duct is this: "See exactly what you are doing, and until you see do nothing." On four occasions I have removed a part of the common hepatic or common bile-ducts, happily not to a degree prejudicing the recovery of the patient, because immediate repair of the duct was performed. If this tragedy should occur it should be redeemed at once. The parts are then all in view, and supple, and restoration is not by any means as difficult as it will prove to be in later weeks or months. It is the surgeon who bungles in this fashion who is then the only sufferer. He feels that the operation has not displayed that degree of ease and mastery in efficient action which stamp the artist; and he has the misery of knowing that he has given less than his best to his patient.

If too much of the cystic duct is removed, and with it a part of the common duct, a stricture of the latter may result. This stricture may itself be responsible for symptoms which closely resemble those of a floating stone, or be the means of causing that degree of stagnation of bile which leads to infection and makes easier the formation of a stone. A few cases have come my way in which a complete segment of the common duct had been excised, and I have had to reconstruct the duct or to anastomose the hepatic duct to the duodenum.

Improper Operations.

At the primary operation upon a case of cholelithiasis when stones are present both in the gall-bladder and in the common duct, the question as to the best procedure to adopt with reference to the gall-bladder will always arise. At a time when operations were performed with difficulty and attended by grave risk, at a time, too, when relief from symptoms after operations by competent surgeons was less frequent than it is now, it was felt that removal of the gall-bladder was unwise. If mistakes were to be made at all, it was safer to make the mistake of leaving the gall-bladder than the mistake of removing it; the former error could be made good, the latter was almost irreparable. But as the quality of surgery improved, and as by degrees we learnt that recurrence of stones in the common duct was so frequently due to recurrence first taking place in a gall-bladder which had only been drained, and that pancreatitis might arise and often probably did arise by extension from the walls of a diseased gall-bladder, the practice of the removal of the gall-bladder grew more common. A study of its walls showed often that they were filled with organisms, and that the elastic and muscular coats were so thoroughly disorganised, and the mucosa so changed, as to render the viscus incapable of adequately fulfilling its functions either as a reservoir competent to discharge its contents on demand, as a regulator of the rate of discharge of bile, or as an organ secreting a constituent which it was proper for the bile to possess on entry into the intestine or otherwise. The cases in which the gall-bladder is needed for anastomosis with the duodenum at a second operation are now so exceedingly few that this consideration need hardly weigh with the surgeon as he reflects upon the course he is to follow.

The present practice of most surgeons whose experience is large is to remove the gall-bladder at the time the common duct is emptied of its stones.

Involvement of the Pancreas.

There are conditions of the pancreas, its chronic or subacute inflammatory states, that may cause a very close mimicry of the symptoms of calculous obstruction of the common duct. The frequency of the association of disease of the pancreas with cholelithiasis is variously estimated by different observers. The pancreatic changes are not easily measured during an operation. It is difficult to gauge the size of an organ so long and so remote with any approach to accuracy; and qualities of texture in respect of hardness, in one part or another, cannot be expressed in terms that make one surgeon's experience comparable with that of another. Removal of a portion of the pancreas is open to the fallacy that the area chosen may not be equally involved with the rest of the organ. But with all due and necessary allowance for these truths there can be no doubt of the frequency, and the occasional grave severity, of the pancreatic changes. The route by which infection reaches the pancreas is not necessarily the same in all cases. The cause of the cholelithiasis may be the cause of the pancreatitis, or the latter may be the consequence of the former. If the pancreatitis is secondary to cholecystitis the infection may travel from the gall-bladder down the common duct, and along the canal of Wirsung; or it may pass in the lymphatic plexus which is common to the two. Some clinical and all experimental evidence (especially Nordmann's) suggests that invasion by the ducts is the more likely; but there is evidence, too, derived from operations, that lymphangitis may be the chief factor in causing the changes in the pancreas. Whichever may be, in any special case, the correct explanation, it is evidently a safer plan to remove the gall-bladder than to drain it. Cholecystectomy is beginning to displace cholecystenterostomy in the treatment of chronic pancreatitis, as a result, chiefly, of the advocacy and practice of Deaver.

The typical symptoms of calculous obstruction of the duct may occur in the absence of calculus. In operating upon such cases it is a little disconcerting to find a distended common duct in which no stone is present. The head of the pancreas, especially, will be found enlarged and hard and œdematous. The duct lies in such intimate relationship with the gland, that a swelling of the latter compresses the duct, causes stagnation of bile, and consecutively a degree of cholangitis that may be very severe. In such cases the T-shaped tube of Kehr may be used to drain the hepatic duct intermittently, or, as I prefer, two catheters may be introduced, one draining the hepatic duct, the other passing downwards into the duodenum and affording the channel by which abundant nourishment may be given.

Operations on Deeply Jaundiced Patients.

All the operations upon deeply jaundiced patients raise two questions—that of hepatic insufficiency and of its avoidance, if such be possible, by an adequate preliminary preparation of the patient, and that of post-operative hæmorrhage. The symptoms due to the failure of the liver are apt to come quite unexpectedly. The operation has perhaps presented no unusual difficulties, and the patient leaves the operation theatre in good condition. For a few days all goes well; then one of two events attract serious attention. The amount of bile discharged may suddenly diminish or almost cease; jaundice deepens slowly; the pulse becomes slower; the mind is clouded; nourishment is sparsely taken or refused, when it is well taken vomiting begins; the amount of urea in the blood steadily augments, the patient grows rapidly weaker, and dies after a period of coma. In these cases, as Walters has shown, it is renal failure consecutive to hepatic failure that causes death. Or the picture so well described by Walters and Parham may be seen.[2]

> "*Clinical Picture of Hepatic Insufficiency.*—Usually the first two to eight days after operation the course is uneventful; biliary drainage and urinary output are normal, fluids are taken well, the pulse and temperature are normal. One of the first signs of the onset of trouble is paling and thinning of the bile with marked increase in the flow. This profuse cholerrhagia does not continue long, but the bile remains thin. STONE IN THE COMMON AND HEPATIC DUCTS.[*]

BY JAMES SHERREN, C.B.E., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL, ETC.

THE presence of stones in the common and hepatic ducts is usually significant of the absence of efficient treatment in the particular patient in whom they are found. They denote failure in carrying out the only satisfactory treatment of gall-bladder disease, early cholecystectomy; this would have effectually prevented their entrance into the ducts. This failure is due to errors in diagnosis as well as inefficient treatment. Patients are still too often treated for various types of dyspepsia; that is, symptoms only are treated, and even after the onset of colic we still see attempts made to avoid operation. There is no medical treatment known at present that will remove the cause of the stone formation or dissolve those already formed; all attempts at such must fail and the ultimate death-rate far exceeds that of the curative surgical procedure. The relative number of cases operated upon at the stage when this complication has arisen must vary somewhat in every district according to the skill and bias of its practitioners and the skill and reputation of its surgeons. The percentage in Sir Berkeley Moynihan's private patients as given at Leeds last year was 21·96 (67 out of 305), differs little from mine, 18·5, which includes both hospital and private cases (113 out of 600).

It is obvious from my opening remarks that I do not believe stones form primarily in the ducts except certain rare pigment calculi associated with disease elsewhere. They may, however, increase in size and in number when infection is present and extend in a continuous column from the ampulla of Vater to the liver and even fill the intra-hepatic ducts. It follows, therefore, that if stones are found in the common duct after a previous operation for gall-stones, they must have re-formed in the gall-bladder, if this was left, or have been overlooked. This is easy unless they are systematically searched for, and even then they may be missed.

Difficulty of Pre-Operative Diagnosis.

Pre-operative diagnosis is only possible in the presence of typical attacks of colic associated with jaundice, often with rise of temperature. Jaundice is usually present at some time during the progress of the case; thus, in the 113 patients upon whom these remarks are based it had occurred in 78, but only in 33 was it severe and present at the time of operation. Many stones may be present in the common duct without producing jaundice and, on the other hand, a transient jaundice may follow an attack of biliary colic and the ducts are found at operation to be clear and the correctness of this confirmed by the subsequent history. In most instances the patient was operated upon for gall-bladder disease and the stones found in the ducts, not by accident but as a result of a definite exploration. Among the 33 cases in whom marked jaundice was present at the time of operation, in 2 it had never been associated with pain; as a distended gall-bladder could be felt the diagnosis of carcinoma of head of pancreas was arrived at. In the majority there was a history of abdominal symptoms extending over many years for which all the recognised forms of medical treatment had been tried.

---

[*] A contribution to a discussion on the Surgery of the Hepatic and Common Bile-ducts at the Royal Society of Medicine on June 27th, 1923.

Most of these cases were operated upon between the ages of 45 and 55, the oldest patient was 76, the youngest 23 with a three months' history. Her first symptom was a typical night attack of biliary colic followed by jaundice, and before I saw her she had had six further attacks. I removed five small calculi from her common duct. She is now 30 and has had no recurrence. It is my impression that stone is more often met with in the ducts in women, probably because of the earlier date at which men seek treatment. In my common-duct series there were 22 men. To compare with this I have taken my last 113 consecutive cases of cholecystectomy with stones in gall-bladder only; 41 were men. I do not think it is extravagant to prophesy that operations on the common duct will become rarities within the next generation of surgeons, as the students educated in the modern methods of treatment of abdominal disease go out into the world.

Treatment.

With regard to treatment, this consists in removing the stones and carrying out cholecystectomy to prevent further stone formation. I shall deal first of all with those cases, and they are the most common, in which operation is undertaken for gall-bladder disease but in which the symptoms give no indication of stones in the ducts. A shrunken gall-bladder, a dilated cystic or common duct, may at once point to its probability. In all these, and in those in whom there is a history of jaundice, after removal of the gall-bladder, the common and hepatic ducts should be explored through the stump of the cystic duct, enlarging the opening by cutting downwards if necessary and removing calculi if found. Before suturing the opening a pair of fine forceps should be passed and the ampulla dilated. The incision should be closed with a continuous stitch of hardened 00 gut and a drain left to the site of incision. This is, in my experience, the most frequent type of operation. Drainage of the ducts is imperative when infection is present or if much manipulation has been necessary in removing the stones. If calculi become impacted they do so in the ampulla, but it is rare indeed that any other approach but that mentioned is necessary for their removal. In only two have I been compelled to open the duodenum to remove such a stone, and on one occasion I mobilised the duodenum and removed an impacted calculus. All these terminated successfully. It has been a common teaching that the gall-bladder is shrunken in most cases of stone in common bile-duct; this is usually so in late cases with obstructive jaundice, but in only 44 of my series was there a small gall-bladder; in five of those with jaundice it was reduced to a fibrous cord without lumen. A dilated gall-bladder does not exclude stone in the common duct.

To pass now to the cases where stones can be palpated in the ducts. I still remove these where possible, by cutting into the common duct from the stump of the cystic. To be *certain* that the ducts are clear is impossible. On occasions, after removing with forceps and scoop what I considered were all the calculi, I have been able to syringe several others from the common and hepatic ducts. When faceted calculi or putty-like masses are found in the ducts this should always be done. Dr. W. J. Mayo[1] has told us that in nearly one-third of the deaths which followed operation on the common duct for stone, post-mortem examination revealed stones which had been overlooked. Among my cases that died at varying times after operation were five in which stones that I had overlooked or been unable to remove were found post mortem; that is, in half of those in whom this examination was done. It is instructive that in four of these the operation had been undertaken for obstructive jaundice, and I believe that had I been content with drainage only, leaving thorough search to a second operation, at least two of these lives would have been saved. In two of these the stone which I had felt in the duct could not be discovered. In two stones were removed but small calculi overlooked in the ampulla. In all, stones in the common duct were diagnosed. In only one had the common duct not been explored, a patient of 39. I removed a gall-bladder containing stones, but did not explore the common duct and have a definite note that "no stones were felt." She died of acute dilatation of the stomach the same night. Post-mortem examination revealed a small calculus in the ampulla. Had I passed a probe, as I should do now with such a history, I should have discovered it but not have prevented her death.

To pass on to the treatment of the most serious group of all, those with obstructive jaundice and usually cholangitis. I believe that it is unwise to operate in this stage unless forced so to do. I mean that the patient should be watched for a day or two, except in those cases with rigors, when immediate operation is necessary. While waiting, saline and glucose should be given per rectum. If the jaundice persists, so making operation imperative, it is well to do it in two stages; it is safer and stones are less likely to be overlooked. If the gall-bladder is distended and the cystic duct patent, cholecystotomy should be carried out; if not, temporary drainage of the common duct, with removal of such stones as present. These patients stand prolonged manipulation badly, and in this way I have been able to bring cases to a successful issue that would inevitably have been fatal if I had attempted to deal with everything in one stage. At the second operation cholecystectomy is done and the stones removed, and the ducts thoroughly examined in a way that is unwise in deeply jaundiced, ill patients.

Prognosis.

With regard to prognosis, there were 11 deaths in the 113 patients, 9 of these were among the 33 who were operated on for obstructive jaundice, and in 4 stones were overlooked. In 2 the ducts were filled with colourless fluid, the so-called white bile. Both recovered, and the excretion of bile was established within 36 hours. It is obvious how delay increases the mortality; the longer the period of jaundice the greater is the risk. In none of these cases did death result from hæmorrhage, and I have not, therefore, found it necessary to resort to preoperative treatment by blood transfusion or the administration of calcium. Three died of lung complications, one under the anæsthetic, the remainder from the tenth to the eighteenth day from hepatic insufficiency. The two deaths among the 80 who were operated upon at a time when they were not jaundiced were due, one to acute gastric dilatation, the other to pneumonia. These figures illustrate how the risk depends on the condition of the patient with regard to jaundice and infection; cholecystectomy for stone where these are confined to the gall-bladder has a death-rate of less than 2 per cent.

What is the ultimate outlook in the patients who have had stones removed from their common ducts? The cases in which I carried out cholecystectomy and in which cholecystotomy had been performed are almost equal. In the first group, 57, there has been no recurrence of symptoms sufficiently severe to need operation and only two in which post-operative colic occurred, and in both it was within a few weeks of operation and did not recur. In one, however, a stone was overlooked and found post mortem. In those in whom the gall-bladder was left further operations were necessary in seven for removal of calculi from the common duct and in one for chronic cholecystitis. The original operation was only done by myself in one of these. The number of stones removed from cases in the first group vary, but even after the removal of hundreds—and in one case the amount was 5 oz.—no recurrence has taken place.

In conclusion, I should like to emphasise the fact that this is an entirely unnecessary complication, and that when the correct treatment for disease of the gall-bladder is carried out we shall cease to have to discuss and carry out operations for the removal of duct calculi.

---

[1] THE LANCET, June 30th, 1923.

GLANDULAR FEVER AND INFECTIVE MONONUCLEOSIS.*

WITH AN ACCOUNT OF AN EPIDEMIC.

By H. LETHEBY TIDY, M.D. Oxf., F.R.C.P. Lond.,
ASSISTANT PHYSICIAN, ST. THOMAS'S HOSPITAL; PHYSICIAN, ROYAL NORTHERN HOSPITAL;

AND

E. C. DANIEL, M.B., B.Ch. Camb., M.R.C.S.

Glandular fever is an acute, infectious, and contagious disease principally of, but not confined to, childhood, characterised by a rapid and marked enlargement of the cervical glands, and by a less constant and less marked enlargement of the spleen, axillary, inguinal, and other glands. There may be some tenderness of the cervical glands, but they are not acutely painful; abdominal pain is occasionally severe. The fauces are often reddened, and a tonsil may be enlarged, but the presence of exudation is unusual and the changes are characteristically slight compared with the marked glandular enlargement. There is no anæmia in the acute stages. There may be a short preliminary period of malaise, the glands appearing about the third day and reaching a maximum in one to three days. With the swelling of the glands there is pyrexia, which is usually about 103° F., but may reach 105° for a day or two; it rarely exceeds 100° for more than a week. The prominent mass of the glands usually subsides in 5 to 15 days, but may relapse or, if unilateral, may occur on the opposite side. Suppuration is extremely rare, and is probably due to secondary infection. Glands in the neck remain palpable for several weeks, or occasionally for months. After the acute stage there is usually a prolonged period of slight depression of health and anæmia which needs attention. Recovery is finally complete and the mortality is negligible.

The most definite complication is a hæmorrhagic nephritis, usually without other manifestations of renal disturbance. Its frequency in well-developed cases is about 6 per cent. The parotid is not affected. The condition has no relation to mumps, whooping-cough, measles, scarlet fever, or tonsillitis, or to leukæmia, Hodgkin's disease, or tuberculosis, or to infections with pyogenic organisms.

Literature of the Condition.

It was first fully described by Pfeiffer in 1889. In an article which Morley and one of us (H. L. T.) published in 1921 the bibliography up to that date will be found. In the last two years attention has been paid, especially in America, to a condition of acute and transient lymphocytosis which has been described as infective mononucleosis. The lymphocytosis is both relative and absolute, and many of the single counts are indistinguishable from those of the early stages of lymphoid leukæmia. Nearly all these cases have occurred in young adults. A few cases under various titles have been recorded in previous years by Türk, Cabot, Deussing, Hall, Ireland and Ruhrah, and others. Ehrlich had met with it, and a search of the older literature under such titles as "acute lymphatic leukæmia with recovery," or "pseudo-leukæmia" would reveal many examples of it. Successful cures have been claimed to depend on various measures, such as the removal of a carious tooth, the occurrence of the lymphocytosis having been ascribed to this abnormality. Series of cases have recently been published by writers in America: Sprunt and Evans in November, 1920, Bloedorn and Houghton in 1921, and Longcope in 1922.

The highest percentage of lymphocytes which has been recorded in these series is in a case of Longcope's—viz., 95 per cent., with a total count of 23,000 leucocytes—a sufficiently startling occurrence. In the case of Ireland and Ruhrah, published under the title A Case of Lymphatic Leukæmia with Apparent Cure, the percentage of lymphocytes was 97·5, with a total count of 20,000. This number of leucocytes has frequently been exceeded. The highest total count in our own experience is 35,000, and the highest percentage of lymphocytes is 85. The clinical manifestations in these cases are indistinguishable from the description given above of glandular fever, and the question arises of the identity of glandular fever and infective mononucleosis.

In 1921, when Morley and one of us went through the literature, no instance was found of a full blood count of a previous case diagnosed as glandular fever. In the case which was then described the lymphocytes rose to a percentage of 85, with a total count of about 15,000. This was the first demonstration of the presence of lymphocytosis associated with a clinical condition recognised as glandular fever. It was considered that the case was identical with the "infective mononucleosis" of Sprunt and Evans. A clinical condition which can be associated with such changes in the blood cells obviously requires recognition and consideration. It is certain that it is frequently overlooked, and it is probably by no means rare.

The special questions which arise are: (1) Is glandular fever a clinical entity? (2) Are glandular fever and infective mononucleosis identical? (3) The relation of these diseases to acute leukæmia and other conditions. Before discussing these questions an account will be given of an epidemic of glandular fever lately under our observation.

An Epidemic of Glandular Fever.

The outbreak occurred in a school for boys between the ages of 8 and 13 years. The school was managed on the usual lines of the best class of preparatory school. The school of 30 boys returned from the holidays on April 27th, 1921. Among the staff was a master, Mr. G., aged 23 years, whose previous movements have been traced without revealing any contact with cases suggestive of glandular fever. On May 12th his neck became visibly swollen on the left side, and the throat was sore, but there was no exudation. Constitutional symptoms were very slight. The prominent swelling subsided in a few days, but the glands remained palpable for a considerable time. Some swelling of the glands was present several days before the 12th, but the date of onset is uncertain.

Also on the same day a day boy was seen in his own home with scarlet fever; his brother (J. B., Case 13) was kept away from school. In consequence of this case of scarlet fever watch was kept in the school for any occurrence of sore throat. On the 23rd two boys reported sick with swelling of the neck and sore throat. Four more cases occurred in the next four days, the last of the six being on the 27th. The clinical condition of all the boys was similar—viz., marked enlargement of the cervical glands, little tenderness, moderate pyrexia, and slight constitutional disturbances. No rash developed. There was no tonsillitis, but in some instances the fauces were reddened. The outbreak was considered to be glandular fever.

No further cases occurred until June 5th, an interval of 9–14 days. On this and the following day 14 more cases developed. Among these was the brother of the boy with scarlet fever, who had returned to school on May 23rd, 14 days previously. Four more cases occurred subsequently, the last being on June 10th. The total number was 24, but it is probable that all the others were slightly affected. Several of the boys had had whooping-cough, mumps, scarlet fever, and measles. The clinical condition, especially in the first group, exhibited the typical manifestations of glandular fever as described above. The epidemic was mild, and constitutional disturbances were usually slight. In no instance did the temperature reach 103°, and in only three boys did it exceed 102°. There was no instance of rigors, sweats, or cough. A transient erythema localised to one flank developed in one boy who had been leaning for a long time on that side, but otherwise there were no rashes. There was a distinct difference in the severity of the first group and the later cases. Of the first group of six, glandular enlargement may be classified as marked in three (Cases 1 to 3), moderate in two (Cases 4 and 6), and slight in one. Of the second group of 18, as marked in two (Cases 7 and 20 in relapse), moderate in six (Cases 11 to 14, 18, and 23), and slight in 10.

---

* A paper read before the Section of Medicine of the Royal Society of Medicine on April 24th, 1923.

Glandular Enlargement.—In all cases this was greatest in the neck. Large visible swellings were present in those classified as marked. In these the main mass was in the usual site, deep to the sterno-mastoid muscle, but other glands in the neck were also enlarged. The prominent swelling was in every case initially unilateral. In these marked cases the swelling usually occurred very rapidly, within 24 hours, and the temperature was at its maximum at the onset. In some instances there were a few preliminary days of malaise. The incidence on the right and left sides was about equal. Pain was slight and often absent, though when large a mass was usually, but not always, somewhat tender on palpation. In the less severe cases the development of the glandular enlargement was more gradual, and was equal on the two sides. Owing to the careful watch which was being kept the cases were recognised very early. In several instances glandular enlargement was very slight at first, and while under observation increased for several days. In these instances the temperature was usually normal, or indeed subnormal, when first recorded and rose with the increase in the size of the glands. The axillary glands were palpable in all the severer cases and some of the milder examples, but never formed a visible mass, and were not tender. The mesenteric glands were palpable in a considerable proportion of the slighter cases. Abdominal pain occurred in several, in one instance suggesting appendicitis. In no case was the parotid affected. In several the superficial submaxillary lymphatic gland was visibly enlarged. The mass of glands diminished rapidly in size and was rarely visible after five or six days, but glands could be recognised on palpation after several weeks. In no instance did suppuration occur, though we feared at one time that it would do so in Case 2.

Fauces.—In no instance was there any exudation on the tonsils. In a certain number the "throat" was complained of, and in these the fauces were reddened profusely and appeared dry, and in several a tonsil was definitely enlarged. In many cases the fauces were unaffected. Several of the boys had had their tonsils removed previously.

Epistaxis.—This occurred in eight cases (Cases 2, 7, 8, 14, 21, 23, 24, and in 20 during relapse). In Case 7 it was profuse and repeated, and in Cases 14 and 20 it occurred several times. It was not confined to the onset. With regard to other symptoms, constipation was not a difficulty, and there was no instance of either diarrhœa or vomiting. The spleen was palpable in only one case (Case 10); the enlargement persisted until the end of the term, but we have since found that another factor was responsible for this. There was no instance of nephritis.

Relapses.—Definite relapses occurred in two instances (Cases 1 and 20); in Case 1 the boy had been taken home for convalescence, but owing to a recurrence of glandular enlargement and pyrexia the parents sent him back on June 25th, four weeks from the onset. In Case 20 the relapse occurred on July 1st, 25 days from the onset. The initial attack was slight and the temperature did not exceed 99·5°. On July 1st the temperature rose suddenly to 102·5°, and the glands enlarged. They reached a maximum in three days, forming prominent swellings on both sides of the neck. The temperature was over 100° for nearly two weeks. In Case 14 there was a slight relapse 21 days after the onset. Until the end of the term it was found that the boys were easily tired and somewhat lethargic both in work and in games, but recovery was finally complete in every instance. Treatment was symptomatic. All the boys are now in good health, two years later.

Examination of the Blood.—There were several difficulties in these examinations. It was necessary to avoid any appearance of "experimenting" on the boys. Some of the earlier cases also were removed by the parents after a few days in order to convalesce at home. A further point was that we were unaware that the lymphocytosis may take time to develop, and also that it may be very transitory; marked changes may occur in a few days. Longcope has referred to this in his article on Infective Mononucleosis. It is evident that a single blood examination may not show any very distinctive change. It was impracticable to take frequent counts on 24 boys, and it would probably have been better to have concentrated on a few cases. Blood counts are recorded in 19 cases. Case 10 must also be excluded as another factor was present. In the records the red blood cells and hæmoglobin are omitted; there was no appreciable degree of anæmia in any instance. The basophils have also been added to the polynuclear neutrophils. In no case was their normal percentage increased and the error is negligible. In no instance was there the degree of total increase of white cells and high percentage of lymphocytes which is recorded in many of the sporadic cases. There is, however, definite evidence of lymphocytosis. The greatest degree occurs in Case 4, who was temporarily removed by his parents a few days later, and in Case 14. It is also distinct in many of the others—e.g., Cases 8, 18, and 20. Case 14 exhibits the development of lymphocytosis. Case 2 is of interest; on May 29th the mass of glands was tender, the separate glands could not be recognised, and the appearance suggested that pus would form. This was the only case in

TABLE SHOWING BLOOD COUNTS OF TWENTY-ONE CASES OF GLANDULAR FEVER.

Case.	Date of onset.	Date of blood count.	Leucocytes per c.mm.	Polymorphonuclear neutrophils.	Polymorphonuclear eosinophils.	Lymphocytes.	Large mononuclears.

NOTE.—The numbered cases occurred in the epidemic. No examinations of the blood were made in Cases 5, 9, 11, 22, and 24.

which we suspected it. It is noteworthy that a polynuclear leucocytosis was present. Suppuration, however, did not occur, though the glands took much longer to subside than in the others. For purposes of comparison blood films have been recently obtained from several of the boys.

M. D., aged 6 years, daughter of the practitioner in medical charge of the school, developed glandular fever on June 10th. She had not been in contact with any known case, which suggests that the infection was conveyed by her father. It must, however, be stated that other cases were occurring in the neighbourhood, and a typical example was seen in consultation with another doctor. The daughter's attack was mild, and she was shortly convalescent. She was then allowed to go to a garden fête on June 29th. Here, contrary to orders, she was kissed by one girl friend, C. R.; this friend alone of those at the party developed glandular fever. Malaise commenced on July 10th, and by July 12th the cervical glands formed a prominent mass; the spleen was palpable, and the temperature 105°. The symptoms were characteristic of glandular fever, and severer than in any case at the school. Two blood counts are given of this case, the lymphocytes reaching 66 per cent. in a total count of 18,000 leucocytes. The attack followed the usual course and recovery was complete.

Sporadic Cases.

In addition to this epidemic eight sporadic cases have been seen which answered to the characteristics of glandular fever. In two instances hæmorrhagic nephritis was present, which brought the patient under observation. Several less definite cases have also been seen. The following are notes of a recent well-marked example :—

C. H., male, aged 3 years, admitted to the Royal Northern Hospital on Dec. 11th, 1922.

History.—Measles. Family history: unimportant. Present illness: for ten days slight malaise and swelling in the right side of the neck and right groin. Passed blood in a stool on day of admission; bowels previously normal.

Condition on Admission.—Face flushed, did not appear ill, no cough, temperature 102°, pulse 118, respirations 32. On right side of neck a prominent swelling due to enlarged glands; apparently not tender on manipulation. Right submaxillary lymphatic gland also enlarged. Right tonsil enlarged, but no exudation and no difficulty in swallowing. Teeth in good order. A few glands in axilla and groin. No mesenteric glands palpable. Liver and spleen not palpable. (Dr. S. W. Harlow, the house physician, is certain that he felt the spleen one day.)

Progress of Case.—Temperature fell to 99° in six days. The prominent swelling in the neck subsided in about two weeks. The submaxillary gland diminished more slowly. Cultures from the fauces were negative for diphtheria bacilli. Recovery was finally complete.

Examination of Blood.†—It will be seen that there is a high degree of lymphocytosis, both relative and absolute (Dec. 15th). On the 20th the percentage of polynuclear cells had risen to 59 per cent., practically owing to the rapid fall in lymphocytes. Subsequently the number of polynuclear and mononuclear cells were about equal, and resembled many of the examinations in the epidemic cases.

The following case may also be recorded :—

J. K., female, aged 9 years. Chicken-pox developed on June 13th, 1922. Doing well until the 19th, when respiration became very rapid and temperature rose suddenly.

Condition on Examination.—First seen on the 20th. Temperature 104°, pulse 120, respirations 40. Looked extremely ill and distressed. Mentally clear; no cough; some cyanosis; no local pain. Became very distressed if moved. Lungs: percussion note definitely impaired at left apex and right base. Breath sounds little affected. No adventitious sounds. The condition was puzzling, but it was suggested that pneumonia was developing.

Progress of Case.—On the left side dullness extended in about 24 hours to the whole lung. Breath sounds were broncho-vesicular, never tubular. No adventitious sounds developed either here or elsewhere in lungs throughout the whole course. No sputum; spleen never palpable; no enlarged glands; fauces clear. After three or four days a slight cough developed, not paroxysmal and never troublesome. Dullness on left now cleared rapidly, at the same time becoming more extensive and definite at right base. No displacement of heart; breath sounds audible and comparatively little altered. About this time very severe abdominal pain commenced, principally in the right upper quadrant. At this stage the patient was seriously ill, the temperature remaining over 104°, pulse about 140, and respirations rising to 60. No diagnosis was suggested which fitted the symptoms and signs satisfactorily. On the sixth day the temperature began to fall slightly.

The next day a younger brother, W. K., rapidly developed a large mass of glands on the right side of the neck. The condition appeared characteristic of glandular fever, and ran the usual course. The diagnosis was then made that in the girl's case there was enlargement of the mediastinal glands with resulting pressure on the bronchi and pulmonary collapse. The abdominal pain would be consistent with the frequency of these symptoms in glandular fever. The girl made a slow but uninterrupted recovery, the symptoms gradually diminishing, and both children are now in good health.

Discussion.

(1) *Is Glandular Fever a Clinical Entity?*—The description given at the commencement of this article applies, practically without variation, to nearly all the severe cases both under our observation and in the literature. It is accurate for the severer cases in the epidemic, for M. D. and for her friend C. R., for the sporadic cases which we have seen, including C. H., for the case published by Morley and one of us in 1921, for Pfeiffer's cases, and for cases since recorded in various countries. It is also accurate for the cases recorded as "infective mononucleosis," as "acute lymphatic leukæmia with recovery," for nearly all the cases of "lymphocytosis due to sepsis," and many cases under similar titles. Atypical and milder cases certainly occur, particularly in adults, and it is noticeable that the later cases in the epidemic were milder and slower in development than the earlier ones. If, for example, we consider the case C. H., it would, we think, puzzle a sceptic to find any other recognised entity under which it could be classified. The symptom-complex is characteristic, distinct from other diseases, and in our opinion sufficient to establish glandular fever as a clinical entity. In typical cases the diagnosis in fact is simple.

(2) *Are Glandular Fever and Infective Mononucleosis Identical?*—It has been stated above that the description of symptoms, progress, and prognosis applies equally to cases recorded under these two titles. Clinically they are indistinguishable. The proof that two separate conditions exist would have to rest on typical cases in which the blood had been followed through the course without the presence of lymphocytosis. No such evidence exists at the present time. It must be noted that it is not impossible for an occasional case to show polynucleosis; this occurred in Case 2 of our epidemic in which we thought clinically that the glands would suppurate. No doubt these acutely enlarged glands may become secondarily affected with pyogenic organisms, and suppuration occasionally occurs. A single count may be deceptive, and it is difficult to know what interpretation one would have put on the blood count on Dec. 20th in the case of the male aged 3. We consider that the evidence justifies the conclusion that an absolute lymphocytosis is the normal occurrence in glandular fever, and that glandular fever and infective mononucleosis are identical.

(3) *Nature of the Mononuclear Cells.*—In nearly all our cases it was very difficult to classify many of the cells as small or large lymphocytes. The main mass of protoplasm is usually greater than is normal in small lymphocytes and stains more deeply. The nucleus is less regular, and is frequently notched and often eccentric. There are no nucleoli. A considerable number of typical lymphocytes are always present. These abnormalities in the lymphocytes have been carefully described by observers of infective mononucleosis and also by previous recorders of such cases. The descriptions are practically all similar, and apply to other cases of glandular fever which we have seen. The nucleus of the most atypical cells have some resemblance to a small-sized Rieder nucleus. It was noticeable that in Case 1 during the relapse the mononuclear cells were

---

† For the examination in this case we are indebted to Dr. E. H. Shaw and Dr. P. O. Ellison. For all others we were personally responsible.

mainly typical large lymphocytes, the differential count on July 6th, 1921, being: large lymphocytes 38·5 per cent., small lymphocytes 5 per cent. In agreement with Longcope, Sprunt and Evans, and others, we consider that the cells are lymphoid in origin. These points are of interest to hæmatologists, but they are not of great importance clinically. We regard the cells as slightly immature lymphocytes. Longcope states that "the leukocytosis is dependent entirely upon an actual increase in the non-granular forms of mononuclear cells." This is almost, but not quite, invariably so. Thus in one of Longcope's cases (Case 6) there was at one time a leucocytosis of 26,200, with 60 per cent. of polynuclear neutrophils. In the case of C. H. here recorded, there were present on Dec. 15th 12,000 polynuclear neutrophils, and on Dec. 20th 14,000. It may also be noted here that a leucopenia may occur. This is mainly due to diminution of granular cells. It is not uncommon for the total leucocytes to be within normal limits.

(4) *Relation to other Diseases.*—The condition we are considering is an acute, infectious, contagious, and transient disease producing an absolute and relative lymphocytosis. From this standpoint the number of diseases we have to refer to is very limited. The numerous chronic conditions which produce only relative lymphocytosis and not an absolute increase need not be considered.

(*a*) So many of the recorded cases had previously had whooping-cough that it cannot be considered that any connexion exists. The same argument also applies to mumps, scarlet fever, and measles, though, of course, in these diseases an absolute lymphocytosis does not occur.

(*b*) There is no evidence that an acute leukæmia is infectious, and so far as we know there is no record of an epidemic. The clinical condition in glandular fever bears no relation to the grave constitutional disturbances of acute leukæmia. Recovery is complete in nearly every case. The clinical differences between the two diseases are so extreme that it is incredible that they can be due to a common factor. Differences between the leucocytes in glandular fever and acute leukæmia have been described, in close agreement, by several observers. While agreeing with these from our own observations, we doubt whether a pathologist, from consideration of these points without other information, could at present give a definite diagnosis between the two conditions, though it may become possible to do so. We may perhaps note that one form of leukæmia in fowls has been proved to be transmissible to healthy animals by inoculation.

(*c*) In infancy there is a tendency for lymphocytes to increase under simple conditions which do not have this effect in older children or in adults, but this has no relation to glandular fever.

(*d*) Certain forms of generalised neoplasm are occasionally associated with lymphocytosis. The condition is neither transient nor infectious, and obviously has no relation to glandular fever.

(*e*) With regard to septic infections, it has been stated above that the fauces are frequently reddened in glandular fever. Sometimes a tonsil may be swollen. This is the usual limit of the changes and any definite tonsillitis is rare. Not uncommonly there is no obvious change and no complaint of sore throat. There is no evidence that oral sepsis or dental caries has any connexion with glandular fever. Sepsis is frequently stated to be a rare but occasional cause of absolute lymphocytosis. In our own personal experience we have never seen an example. So far as we can ascertain this is based almost entirely on articles by Türk in 1907, by Marchand and by Cabot in 1913, and by Deussing in 1918. Study of these articles reveals no evidence for the statement. The cases of which clinical data are given can be divided into two categories—cases of acute leukæmia which were fatal, and cases of glandular fever which recovered. A striking point in these articles is the frequent absence of any evidence of sepsis. Another point is the absence of recognition that in acute leukæmia the leucocytes are frequently not increased in number. In 24 cases of acute leukæmia, which Panton and one of us (H. L. T.) published in 1914,‡ there were 11 cases in which counts of under 10,000 were recorded, and six cases of counts under 4000. Absence of recognition of this leucopenia has led many writers to attribute the leukæmia to some subsidiary septic lesion. In our opinion the statement that sepsis occasionally produces lymphocytosis is without foundation.

(5) *Nephritis.*—The amount of blood which is passed has struck most observers, especially as the usual symptoms of nephritis are certainly generally absent. The prognosis is good. It is doubtful whether a typical attack of acute nephritis ever occurs; there is no record of such an occurrence in the literature, though the condition of the urine suggests that the kidneys must sometimes be definitely affected. Little is known about this complication, which is worthy of consideration from the standpoint of nephritis.

(6) *Degree of Infectivity.*—It is difficult to arrive at a conclusion on this point. Cases have been nursed in hospital wards without special precautions, but we have never seen an instance of infection in such circumstances. It is usually stated that the incubation period is commonly seven or eight days, but the epidemic here described suggests that it is more often 10 or 12 days.

Diagnosis.

In glandular fever attention may be directed especially to the mildness of the constitutional symptoms even when the temperature is high, to the rapidity with which the glands enlarge, to the very prominent mass which they often form, and to the absence of anæmia. In one of these cases (W. K.) it is certain that the glands were not enlarged to any extent in the morning, while in the evening they formed a mass almost the size of a fist.

Acute Leukæmia.—A diagnosis is not difficult on clinical grounds. In acute leukæmia the patient is seriously ill, while in glandular fever the constitutional disturbance is nearly always mild, especially in comparison with the enlargement of the glands. An equally important point is the absence of anæmia. On the examination of the blood it would be impossible in some of the cases for a pathologist to make a definite diagnosis between leukæmia and glandular fever, but, on the other hand, it is improbable that any clinician bearing glandular fever in mind would make a mistake between the two diseases. Even apart from recollecting glandular fever, leukæmia would rarely suggest itself. The medical man who sees a case thinks not of leukæmia but of mumps or of tonsillitis. He is usually somewhat puzzled, and while he is puzzling the glands subside and the patient recovers. Sometimes he removes a carious tooth, and recovery is ascribed to this. The transient nature of the marked swelling and the usual absence of severe symptoms is the reason why the blood is so rarely examined in a condition which is comparatively common.

Mumps.—Outbreaks of glandular fever and also sporadic cases are frequently diagnosed as mumps, or perhaps even more commonly as "aberrant mumps." We have never seen the parotid gland affected in glandular fever, but the pre-auricular lymphatic gland may enlarge, and the superficial submaxillary lymphatic gland often attains a large size. The absence of pain is a practical difference. A mistake in diagnosis between these conditions would in point of fact be of little importance.

Tuberculosis.—There is no doubt that some cases of glandular fever have been diagnosed as "acute tuberculous adenitis." The serious results of such an error are obvious. The recognition of the existence of glandular fever should be sufficient to prevent a mistake which may affect an important period in a child's life. The diagnosis of "acute Hodgkin's disease" has also been made.

---

‡ Quarterly Journal of Medicine.

Tonsillitis.—Septic tonsillitis is often extremely infectious. The constitutional symptoms are usually severe, suppuration is common, and there is a considerable mortality. Simple tonsillitis is, of course, very common, and if anyone who is subject to it contracts glandular fever there may be a co-existent tonsillitis, but the striking point in glandular fever is the slightness of the changes in the fauces compared with the marked enlargement of the glands. It is obvious that the causes of local sepsis in the scalp and elsewhere must be searched for and excluded as far as possible.

Conclusions.

1. Glandular fever is a clinical entity.
2. An absolute lymphocytosis is a normal occurrence.
3. Glandular fever and the condition described as infective mononucleosis are identical.
4. Recovery is permanent, and there is no relation to leukæmia, Hodgkin's disease, or tuberculosis.
5. There is no evidence that sepsis is a cause of absolute lymphocytosis.

TRAUMA AS A POSSIBLE CAUSE OF BRAIN TUMOUR.

BY ERNEST S. REYNOLDS, D.L., M.D., F.R.C.P. LOND.,
EMERITUS PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF MANCHESTER: CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

IT is a common occurrence for parents to ascribe an injury to the head as the cause for mental deficiency, epilepsy, infantile diplegia and hemiplegia, anterior poliomyelitis and other nervous affections—such injuries, which most individuals suffer from sooner or later in greater or lesser degree, having, however, nothing whatever to do with the disease in question. The only exception to this would be a true traumatic epilepsy from direct injury to the motor cortex, or where a blow on the head, possibly only slight, seems to be the exciting cause of starting essential epilepsy in a predisposed subject.

One is thus prejudiced against considering blows on the head as causes of cerebral disease, including cerebral tumour. But cases arise from time to time which make one wonder whether injury to the head may not after all be a causative factor of brain tumour. Medico-legally this point is of the greatest importance. One may "think" a head injury has caused a tumour, but legally the opinion given must be beyond "mere surmise, conjecture, or guess."

Literature of the Subject.

On looking up authorities one is surprised to find how indefinite opinions are as a rule. Thus Gowers[1] says: "There is little doubt, however, that traumatic influences, falls and blows on the head, are occasionally the immediate excitants of a growth, since the symptoms have been observed to follow a blow, and the tumour is found to correspond in position to the seat of the injury. Such a relation has been observed in almost all forms of tumour, especially in syphilitic and tubercular growths and in sarcomata of the dura mater. . . . Apparently the nutritive changes consequent on a mere concussion may be the starting point of a tumour. In some cases local symptoms of irritation, which were continuous with those of a subsequent tumour, commenced two or three days after the injury. . . . But the cases in which a traumatic cause can be traced form a very small proportion of the total number and the extent of this influence may readily be overrated. It should be remembered that a fall may evoke symptoms which existed before the accident."

Ross[2] says: "Injuries of the skull act as exciting causes in the production of cerebral tumours. Several cases have come under my own observation in which the disease dated from a blow on the head, and the tumour in these cases frequently grew at a place corresponding to the seat of injury." Byrom Bramwell[3] says: "Traumatic injury is in some cases undoubtedly a proximate cause [of tumour], especially in the case of tuberculous, syphilitic, and gliomatous new growths." Van Gehuchten[4] says: "Dans certaines circonstances on tend à incriminer le traumatisme, surtout pour les gliomes et les sarcomes, mais l'influence du traumatisme sur l'éclosion des tumeurs cérébrales est loin d'être prouvée."

In considering this question I have gained much valuable information from Prof. James Ewing's book, "Neoplastic Diseases," and from it I take the following statements and references. He says:

> "There seems to be no sufficient reason for denying the relation between trauma and many chondroma, osteoma, lipoma, fibroma or fibro-myxoma with which the history of a blow is rather common—also with the most striking forms of traumatic tumour, gliosarcoma and osteosarcoma where a definite history of injury is frequent. To establish relationship several classes of evidence are necessary, as is recognised especially by French statutes: (1) The authenticity and sufficient importance of the trauma; (2) previous integrity of the part; (3) a reasonable time-relation, three weeks to three years; (4) continuity of pathological changes or symptoms in the wounded part and the appearance of the tumour; (5) microscopic proof of the existence of the tumour. When a healthy adult receives a blow on the head, remains unconscious for days, never recovers full mentality, shortly develops signs of brain tumour, and dies in a few months of gliosarcoma—the liability is generally accepted as complete."

Gerhardt gives 10 in 60 reported cases; Adler[5] in over 1000 cases gives 8·8 per cent. as due to trauma, and details 118 cases of various types, illustrating many possible relations to trauma, some of them quite direct. Trauma may be a direct exciting cause of the tumour as shown by the injury causing a lesion of the dura or pia with affection of brain tissue. Less satisfactory and more numerous are those cases in which the tumour appears at some point remote from the injury. Starr assumes, probably correctly, that a cerebral hæmorrhage or contusion may pass directly into a tumour process.

Mr. Geoffrey Jefferson, hon. surgeon to the Salford Royal Hospital, who is specially interested in neurological surgery, tells me of the following case:—

> A woman, aged 35, fell against a piece of machinery, striking the right side of the head; she ever after suffered from headaches over the vertex and then very severe in the sub-occipital region. She then commenced with occasional vomiting and sometimes to fall backwards, and her eyesight began to fail. When Mr. Jefferson first saw her six months after the injury, she could not stand without support, leaned heavily backwards, saying she was afraid she was going to fall on her face, said the room was spinning round from left to right. There was double optic neuritis and nystagmus rapid to right, slow to left; no ocular paralysis, but slight numbness of left face. A bilateral sub-occipital trephining was performed; no tumour was found, but she died the same evening from shock. At the autopsy a right-sided glioma involving the midbrain and with an extra-cerebral projection of growth which lay between the tentorium cerebelli and the upper surface of the right lobe of the cerebellum; the growth also involved the posterior part of the substance of the right hemisphere.

[4] Les Maladies Nerveuses, p. 467.

[5] Arch. f. Unfallheil., 1897, ii, 189.

Mr. Jefferson tells me that he has had under his care about 1000 cases of injury of the head, civil and military, and of these has only seen three cases of brain tumour. He doubts if a single trauma can start a growth and thinks it more likely that when it apparently does so it is only by "stirring up" a growth which was already present.

Personal Experience.

I regret that I cannot give definite statistics of my own, but I can certainly say that very seldom in my personal practice have I been able to ascribe brain tumour to injury. The two following cases are of interest:—

Case 1.—In November, 1898, a finely built man, aged 46, consulted me. Three years previously he had a fall on the back of the head while skating and he was stunned for a time but not definitely unconscious. Two years afterwards he commenced with pain at the back of the head with some giddiness. In July, 1898, he found his right foot would not quite respond to his will and in August he could not write as well as usual; in September he was somewhat unsteady in gait and had acute pain at the back of the head; then found a difficulty in pronouncing words and in clear articulation. He had no vomiting.

Condition on Examination.—When I saw him he was slightly unsteady in gait and when standing with the eyes closed reeled over backwards and to the right; there was pain and some tenderness at the back of the head; the right knee-jerk was more lively than the left, and there was some slight weakness of the right arm and leg; his speech was a dysarthria (not an aphasia); pupils and optic discs were normal; no tremors; but writing very irregular, and both hands ataxic and awkward on attempting fine movements.

Course of Case.—A diagnosis of a tumour of the middle lobe of the cerebellum was made. I saw him again in ten days when he told me he had had three sudden attacks of vomiting. A few days after this he became rapidly worse with some stupor, emotionalism, and standing and talking were impossible. The late Sir William Thorburn operated on Dec. 23rd, trephining the left side sub-occipital region; the dura mater bulged greatly into the wound and was opened on Dec. 25th with a great discharge of clear fluid but no tumour was found. The patient became more sensible for a few days, then coma set in and he died on Jan. 1st, 1899.

Post Mortem.—A soft myxoglioma, the size of an average walnut, was found in the middle lobe of the cerebellum, three-fifths of it being to the right and two-fifths to the left of the middle line.

Case 2.—On May 22nd, 1922, I was called to see in consultation a well-built, healthy-looking Jewish gentleman, aged 35, and was told that on March 24th, 1922, he had been knocked down by a motor-car and received bruises on the right hip and right side of the head; he was stunned but able with assistance to get home, only about a quarter of a mile away. After a few days rest he went to Blackpool to convalesce, but returned no better.

Condition on Examination.—When I saw him he merely complained of tingling and numbness of the left side of body and limbs with some headache. He was very nervous about his condition and very emotional, thought the right side was also getting affected, and said he was sure he was going "to have a stroke and would become lifeless." A full examination, including, of course, the optic discs, revealed no abnormal physical signs and no loss of sensation could be detected, and I considered that he was a case of traumatic neurasthenia.

Course of Case.—He returned to Blackpool and while there began to lose power on his left side. On returning home he went to the Manchester Royal Infirmary and after examination in the out-patient department was considered to be a "functional" case, but he was sent into the wards and detained there for seven weeks. During this time the left hemiplegia slowly became worse and he was taken home by his wife on August 3rd, 1922, and I was asked to see him again on that day. He was then very ill, slightly delirious, with total left hemiplegia and hemianæsthesia, immobile pupils, and double optic neuritis. On August 14th Mr. Jefferson trephined over the right motor area, there was intense bulging of the brain into the wound, but nothing definite was found. The patient died the next day.

Post Mortem.—A soft gliosarcoma was found in the right optic thalamus and invading the internal capsule. At the inquest it was considered that the tumour had no connexion with the accident, but the friends commenced a civil action which was settled out of court by the insurance company paying £550.

It is most difficult to decide whether these cases really show any causal relation between trauma and tumour, or whether they are examples of that frequent and incalculable factor in estimating causation—namely, coincidence.

I have brought this question forward in the hope that others will make full inquiry regarding any comparatively recent injury to the head in cases of brain tumour and to elicit the experience of others.

Clinical and Laboratory Notes.

TWO CASES OF
ENCEPHALITIS LETHARGICA
WITH SCARLATINAL DESQUAMATION.

By J. Lumb, M.B., B.S.Durh., D.P.H.,
LATE MEDICAL SUPERINTENDENT, EAST DENBIGHSHIRE FEVER HOSPITAL.

Two cases of encephalitis lethargica under my care have both presented the feature—unusual so far as I am aware—of desquamation closely simulating that of scarlet fever.

Case 1.—A young man, aged 17, employed as a fitter at a large omnibus garage, complained first of pain in right knee, thought to be a sprain caused while cranking up a 'bus. A week afterwards he developed acute mental symptoms, delirium and excitability, part of the delirium taking the form of "*occupational soliloquies.*" Removed to the union infirmary as a mental case, and remained there for several days. It was then noticed that his hands were undergoing the typical "glove" peeling so characteristic of severe cases of scarlet fever. His toes also showed signs of desquamation. I was requested to see him with a view to confirming the diagnosis of scarlet fever. After some hesitation I agreed to admit him to the Wrexham Fever Hospital, as there was an indefinite history of vomiting and sore throat some weeks previously. This has since proved incorrect.

On admission, on March 2nd, 1923, to the East Denbighshire Fever Hospital, all acute mental symptoms had disappeared. He was very somnolent, waking up only when roused at meal-times, &c. Superficial and deep reflexes were present, but sluggish. There was incontinence of urine. Sane answers given to questions, but in a slow and hesitating manner. Memory very poor. Desquamation on hands complete in about a week, but contrary to what would have taken place in scarlet fever the dead skin came away in small pieces and left behind a roughish surface. No desquamation elsewhere except over a small area in the dorsal region of the back. Somnolence and lethargy lasted for two weeks, and was followed by a short period of irritability. Recovery is now almost complete, except for a certain listlessness and slurring speech. Described by his mother as having been a very bright and cheerful boy before this illness.

Case 2.—Admitted to the Wrexham Fever Hospital on March 10th, 1923, from the Wrexham General Infirmary as a case of encephalitis lethargica. He appeared to be a fairly typical case with marked somnolence, ptosis, nystagmus and diplopia. waking up when spoken to, and answering questions in a slow monotonous voice. Quite fair appetite; reflexes normal except Babinski + in the right foot. Incontinence of urine at first, ceasing as lethargy passed off. Shortly after admission his feet, hands, and legs commenced to desquamate, not quite so markedly as in Case 1, but sufficiently so to make it a fairly typical "glove" desquamation of scarlet fever. As in Case 1, there was no peeling on the neck and chest. After peeling the palmar surface of the hands and the plantar surface of his feet presented the same rough appearance as in Case 1. This case is running a protracted course, but practically all visible skin changes have now ceased.

I have been unable to find any similar case of such marked desquamation recorded in the literature on encephalitis lethargica. In the report of Dr. A. C. Parsons to the Ministry of Health there is, however, what may be a parallel case (Case 673/1919). Here it had been noted that there was a faint rash on the chest, and this was followed by desquamation—the inference drawn being that the case was one of encephalitis lethargica combined with scarlet fever. I venture to suggest in the light of the two cases I have had under my care that desquamation may be added to the already manifold signs of encephalitis lethargica. The close similarity of the desquamation to that occurring in scarlet fever might deceive anyone not well acquainted with the latter disease; but, as I have pointed out, the appearance of the skin after desquamation had taken place was sufficient to show that the peeling was not that associated with scarlet fever.

London.

A NOTE ON A
HELMINTH SURVEY OF A GURKHA BATTALION.

BY R. C. WATTS, M.D. LIVERP., D.P.H., D.T.M.,
CAPTAIN, I.M.S.

THE original idea of the work undertaken was an investigation of ankylostomiasis among Gurkha soldiers who come from a part of India where the disease is prevalent.

Procedure.—A number of labels bearing men's names, numbers, &c., were distributed daily amongst the Gurkha Rifles. These men were instructed to defæcate into clean latrine pans set apart for them. After defæcation the man handed over his label to the sweeper, who took a specimen of the fæces in a gallipot, labelled it, and sent it to the laboratory. In this way the whole unit was examined.

The concentration methods were not used as they take too long, and are not practicable with restricted facilities. The ordinary method of dissolving a loopful of fæces in normal saline and putting under a cover-slip was used. The results are summarised as follows: Number of cases examined, 561; number of cases infected, 139 (ankylostomiasis, 8·5 per cent.; ascariasis, 12·2 per cent.; trichocephaliasis, 4·6 per cent.).

The routine method used in the laboratory was as described above, but an observation was also made as to the effect the harbouring of worms had on the human host. The cases can be divided into three categories: (1) Cases having infection without being inconvenienced or showing any signs whatever; (2) cases having some other diseases which may mask signs of helminthic infection; (3) cases in which anæmia is marked. Though no definite figures can be given, a rough estimate under the above classes is: (1) 81 per cent., (2) 17 per cent., (3) 2 per cent.

Results.—Recruits taken by themselves showed an infection with ankylostomes in 20 per cent., but owing to good sanitary conditions in the lines individuals are not reinfecting themselves or infecting others. Probably this is the reason why the men with longer service show a smaller percentage of infection than the younger men. Though it is well known there are many who harbour ankylostome worms and enjoy good health, yet at some time or other the parasites may produce serious effects. For this reason treatment was carried out. Men were taken into hospital and treated with 60 gr. doses of thymol. The stools were examined for worms, which were collected for examination. It was found that all the worms were *Necator*, and that on the average three doses of thymol were required before a patient's stools were free of ova.

In conclusion, I have to thank Lieut.-Colonel H. M. Cruddas, I.M.S., for valuable suggestions.

Abbottabad, India.

QUEEN'S UNIVERSITY OF BELFAST.—The Marquis of Londonderry has been elected Chancellor of the University in succession to the Earl of Shaftesbury, resigned. The election, which rests with the Members of Convocation, was unanimous.

THE FLOWER HOUSE, CATFORD.—On Saturday, July 14th, Sir Henry Fielding Dickens, K.C., will lay the corner stone of an extension to accommodate invalid ex-officers at the Flower House, Catford, S.E. 6, when there will be a reception by Major Pat à Beckett and Major and Mrs. Walter à Beckett at 4.30 P.M.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

SURGERY OF THE HEPATIC AND COMMON BILE-DUCTS.

A MEETING of this section was held on June 27th, with Mr. JAMES BERRY, the President, in the chair, when Dr. WILLIAM J. MAYO opened a discussion upon this subject. Dr. Mayo's paper was published in THE LANCET last week, and the contributions of Sir BERKELEY MOYNIHAN and Mr. JAMES SHERREN, who followed, will be found on pp. 4 and 7 of our present issue.

Mr. G. GREY TURNER referred to

Cases of Surgical Injury to the Larger Bile-Ducts

which had occurred in his own practice. Case 1 was operated on for gall-stones; the gall-bladder and duodenum were wrapped in omental adhesions, during the separation of which an unsuspected diverticulum of the duodenum was opened. This was temporarily clamped and the gall-bladder, which was full of stones and apparently of hour-glass form, was removed after exposing what was thought to be the cystic duct. After the removal of the gall-bladder there was a leakage of bile, and investigation showed that the common duct had been inadvertently divided. The duodenal diverticulum, which contained a pancreatic process in its wall, was excised; as this caused considerable narrowing of the gut, the pylorus was occluded and a posterior gastro-enterostomy was performed. Investigation of the bile-duct injury then showed that at least an inch had been excised, but the ends were easily brought together and united by end-to-end suture. The patient unfortunately died of a duodenal and pancreatic fistula four weeks after operation. At the necropsy the bile-duct was found intact, although the parts were much altered by auto-digestion; other diverticula were found springing from the duodenum and upper three feet of the jejunum. Had it not been for the other complications the patient would probably have survived the injury to the bile-duct.

In Case 2 cholecystectomy was performed for gall-stones, what was taken for the cystic duct being ligatured in the usual manner. A biliary fistula appeared after operation, but this had healed on discharge from hospital three weeks after operation. After discharge the biliary fistula recurred, but healed after a month, the healing being followed by jaundice and severe pain. Four months after operation the patient, now deeply jaundiced, was readmitted, and after a few days' preparation the abdomen was reopened. After freeing the region of the biliary ducts from adhesions, the lower end of the common bile-duct, which had been divided in the first operation, was found just above the duodenum. The upper end was, after great difficulty, identified in a mass of dense scar-tissue under the liver by puncture with a hypodermic needle. During this dissection the cystic artery was injured and had to be secured by a clip, which was left in situ at the end of the operation as it was impossible to ligature the vessel. The ends of the duct were then fairly easily approximated over a rubber tube after Sullivan's method. The patient, who had stood the operation quite well, died in 48 hours from hæmorrhage into the abdominal cavity and into the cellular tissue about the hepatic omentum, duodenum, and pancreas. The junction of the bile-duct was satisfactory, but the rubber tube had been introduced too far, and had passed up the left hepatic duct to the centre of the liver. It was obvious that a mistake had been made in attempting to perform an anastomosis in the presence of deep jaundice; the indication was to open and drain the hepatic duct, and to leave the repair till a later occasion.

Case 3 was that of a stout female, aged 41, operated upon for recurrent gall-stones, cholecystectomy and gastro-enterostomy being performed. A bile fistula persisted for two weeks, and after it closed the patient became thin, developed a pale-lemon colour, and passed clay-coloured stools. Occasionally she had pain with pyrexia and definite jaundice, although in the intervals she was fairly well. A diagnosis of an increasing stricture of the common bile-duct became obvious and the biliary apparatus was explored at a second operation nearly two years after the first. The common duct was, with some difficulty, identified and opened below the obstruction, where the lumen was so narrow that a fine probe only could be passed. The stricture was divided and the duct reconstructed by a modification of Sullivan's method. Bile was discharged from the wound for a fortnight, and even when the fistula closed did not find its way into the intestine in any quantity. Three months after the operation the patient was, however, much improved; the fæces were of normal colour, but the tube had not appeared. The remarkable feature of the case was the fair health of the patient in the interval between the two operations, in spite of a severe stricture of the common duct.

Case 4, a male, aged 36, had a cholecystostomy performed as an emergency operation in February, 1922, his condition at that time precluding any more extensive operation than the removal so far as possible of stones and drainage. Although recovery followed, further attacks of gall-stone colic necessitated a further operation three months later. On this occasion cholecystectomy was performed with considerable difficulty owing to rigidity of the powerful abdominal muscles and the obscurity of the parts from adhesions. At the operation it was recognised that a small portion of the common duct had been excised; this opening was used to extract stones from the lower end of the duct and was then sutured. On the removal of the support behind the loin the parts came well together, but some bile leakage persisted for three weeks; after four weeks he was able to return home apparently cured. Shortly afterwards the wound reopened and discharged bile, and in spite of this he had pyrexia and persistent jaundice. Accordingly he was readmitted ten weeks after the last operation. After three days spent in preparation, the abdomen was again opened. There were very dense adhesions between the under surface of the liver and the situation of the bile-ducts, and the sinus had to be traced through these to the upper end of the common duct. The latter had become obliterated at the site of the injury and all the bile was finding its way through the fistula. In this case the lower end of the duct could not be identified, so the upper part was therefore anastomosed to the duodenum which had to be mobilised to allow union to be made without tension. The crescentic opening in the duodenum wall was at least half an inch in length and mucous membrane was united to mucous membrane. A small rubber drain was brought to the surface from the neighbourhood of the union. Two days after the operation there was distinct jaundice, but this soon passed off and in three weeks the patient was very well, the wound was healed, and the fæces contained a normal amount of bile. Two months afterwards he had a slight attack of pain with transient jaundice. These attacks were repeated and five months after operation he had a severe one accompanied by a rigor. This unfortunate man was accordingly readmitted in January, 1923. He was then slightly jaundiced following a recent attack. Because of the intermittent nature of the attacks and the comparatively good condition between them, the question of the possibility of further stones in the common duct was raised, and yet another operation was advised and was carried out on Feb. 3rd, 1923. The region of the duct was exposed with difficulty. No stones were felt and the duct was not dilated enough to identify or to incise. The duodenum was therefore opened and after great difficulty the new opening of the common bile-duct was found. It was very tiny, only admitting a fine probe; this was followed by bougies, until the opening easily admitted a No. 10 catheter. A portion of the latter was left in situ and fixed by a stitch. An artery was divided which could only be secured by clips left in situ. During convalescence there was slight bile leakage, pyrexia, and a tinge of jaundice. Early in June he was very well.

Points Affecting the Repair of Surgical Injuries.

These cases were quoted in order to demonstrate how much care should be exercised to avoid injury to the bile-ducts, and how, in spite of opinions to the contrary, the tendency after injury to the ducts was towards obliteration or stricture rather than towards restoration of function, even when immediate steps were taken to repair the injury. The multiplicity of operations described for the repair or reconstitution of the bile-ducts suggested that injury to them was not uncommon. Surgical injury could only be avoided by the identification of the hepatic and common ducts before the supposed cystic duct was clamped and divided. In dealing surgically with the larger bile-ducts the following facts should be borne in mind. (1) The ducts are elastic, and not only retract when divided but their ends also contract, thus favouring obliteration. (2) Except when fixed by inflammation they lie loosely among tissues which form a natural sheath in which hæmorrhage or extravasation of bile tends to be confined—the former aiding the obliterative process. (3) The mucous membrane has great recuperative power and tends to grow out along the duct, and is therefore very helpful in bridging a gap. (4) Ducts do not atrophy appreciably or become obliterated from disuse, but only as the result of inflammation. These considerations showed that the most important point in repair was to secure approximation of the ends of the ducts. The suture line should be the widest part of the duct, and too many sutures should not be employed as they were apt to cause narrowing. It was better to avoid the contact of any foreign body with the suture line. In these operations every possible aid to exposure should be employed; while the importance of the Mayo Robson position was universally recognised, the assistance given by the "reversed Trendelenburg" position was not so generally known.

Exploration of the Ducts.

He could not agree with his former master, Sir Berkeley Moynihan that it was unnecessary to open the common duct when symptoms pointed to the presence of stones, as small stones and soft detritus might easily escape detection by external palpation. When the duct was not large enough to admit the best probe, the finger, he employed the Desjardins forceps both for exploring the duct and for the removal of stones. The operation could not be considered complete, as the opener (Dr. Mayo) had taught many years ago, until a sound had been passed from the opening into the duodenum; for this purpose the speaker employed a female bladder sound three-sixteenths of an inch in diameter, thus dilating the opening of the bowel and ensuring the escape later of any stones missed during operation. The success of this manœuvre was indicated by the common occurrence of one attack of colic during convalescence. While he was interested to hear the remarks of Dr. Mayo as regards suture of the opened ducts, his own experience led him to regard drainage as the safer proceeding in any case of doubt. The greatest advances in the surgery of this region of recent years had been rather in the choice of the time for operation and in the preliminary and after-treatment than in the actual operative technique. He was convinced that the two-stage operation would save lives in the very toxic or jaundiced cases, but the need for this measure was growing less with earlier recognition of gall-stone disease and earlier operation.

Mr. Turner then described a specimen, shown at the meeting, of an enormous cystic dilatation of the common bile-duct, due, he suggested, to valvular obstruction which acted in similar manner to the valvular obstruction of the ureter, producing hydronephrosis. He also suggested that the enormously dilated common ducts sometimes seen associated with only small gall-stones, or none at all, were congenital anomalies allied to the congenital dilatation seen sometimes in the colon or ureters without any obvious cause. A further anomalous condition he had seen was the leakage of bile from apparently intact ducts sometimes associated with pancreatitis but occasionally without. Mr. Turner also suggested that the investigation by making plaster or gelatin casts of the lumen of the common bile-duct, to discover or disprove the presence of pouches in which stones might be overlooked, might be a useful field of study for surgical anatomists.

Reconstruction of the Ducts.

Mr. A. J. WALTON said that in these days, when so many operations were being performed in this region, it was essential that surgeons should have a clearly defined line of procedure for reconstruction of the ducts. Such an operation might be required for several conditions.

1. *Accidental Injury to the Common Bile-duct.*—Pathological lesions of the gall-bladder frequently led to changes in the anatomy of the parts which normally showed considerable variations in the origin and course of the cystic artery and in the length and position of the cystic duct. These variations, normal and pathological, unless they were well known, frequently led to injury to the common duct in the operation of cholecystectomy, which was now almost universally advocated as the operation of choice in gall-stone disease. The cystic artery might lie in front of the cystic duct; its unexpected division and retraction into the gastro-hepatic omentum led to the obscuring of the parts by hæmorrhage, and attempts to clip the vessel in the depths of the wound might easily lead to the inclusion and crushing of the common duct in the grasp of the forceps. Again, the cystic duct and the common duct sometimes ran parallel and were closely adherent; in this case both ducts might be divided, the common duct being mistaken for a portion of the cystic duct. When it was the more usual practice to remove the gall-bladder from the fundus backwards tension upon the freed gall-bladder might result in a loop of the common duct being pulled up and completely excised. As a result of inflammatory adhesions Hartmann's pouch of the gall-bladder might be firmly attached to the common duct; an incomplete dissection would then lead to the division of the common duct in mistake for the cystic. The only way to avoid these accidents was to make it a definite rule that in performing cholecystectomy nothing was divided until all three ducts, the common hepatic, the cystic, and the common bile-ducts, had been exposed by an incision in the upper part of the gastro-hepatic omentum. It was equally important that the cystic or any abnormal artery should be ligatured before it was divided.

2. *Congenital Absence of the Cystic Duct* was a very rare condition which necessarily involved removal of a portion of the common bile-duct during the operation of cholecystectomy. This should be observed and the continuity of the ducts restored at the time.

3. *Early Pancreatic Obstruction.*—In cases of this kind, when the gall-bladder was the seat of inflammatory disease or contained stones, the operator might proceed to remove the gall-bladder, failing to recognise an obstruction to the common bile-duct lower down. Later the line of suture might give way, leading to a permanent biliary fistula. At the second operation the lower portion of the duct was collapsed and might be so fibrous as to be undiscoverable; some operation would then be necessary to unite the upper patent end of the duct to the duodenum.

4. *Advanced Cases of Chronic Pancreatitis and Carcinoma of the Head of the Pancreas.*—As a rule these cases were associated with deep jaundice, a distended gall-bladder containing dark bile, and a dilated common duct as well as a hard and nodular pancreas. Rarely, however, long-continued obstruction led to absorption of the bile pigments, so that the bladder and passages were filled with mucoid-like fluid; if the gall-bladder were aspirated this condition was liable to be mistaken for obstruction to the cystic duct and the common duct might be opened to settle the diagnosis. There was then a danger of leakage from the common duct even if the opening were closed by suture and the pressure relieved by a cholecystenterostomy. A second operation to cure the biliary fistula would show an atrophied and fibrous lower end of the duct, the upper part alone being patent.

5. *Combined Disease of the Gall-bladder and Common Duct.*—It was important to realise that a growth in the bile passages might coexist with gall-stones and even with a carcinoma of the gall-bladder. In Mr. Walton's 262 cases of cholelithiasis there were seven cases of carcinoma of the gall-bladder, ten of the common duct alone, and five of carcinoma of both the common duct and gall-bladder. Carcinoma might occur at the junction of all three ducts, in the common hepatic duct above the cystic duct, in the common bile-duct, or at the ampulla. In the former two cases cholecystenterostomy would not relieve the obstruction, and in the latter two cases cholecystenterostomy would only be suitable with a healthy gall-bladder; when the gall-bladder was diseased or collapsed the only feasible operation was the anastomosis of the duct to the duodenum.

6. *Obstruction of the Duct by a Scar.*—It was stated as an objection to the routine performance of cholecystectomy that the gall-bladder was no longer available for cholecystenterostomy should the common duct become obstructed later. Such obstruction was very rare.

Operative Technique.

The operations to be performed for any one of the above conditions were numerous, and would naturally differ according to whether the duct were dilated or leaking. The operations of choice were the following.

1. *Direct Suture.*—In cases of surgical injury to one of the ducts, and sometimes when a small carcinoma had been excised, this would appear theoretically to be the operation of choice. As a matter of practice, however, direct suture was often a matter of difficulty, the ducts being small and in the case of obstruction of uneven calibre, and for this reason suture was often conducted around a tube the removal of which was again difficult. Further leakage was not uncommon and stenosis was likely to occur; the latter had occurred in a mild degree in Mr. Walton's one case of the kind.

2. *Lateral Choledochoenterostomy* might be performed in those cases where the obstruction was low down and the duct considerably dilated, the duct being anastomosed to the duodenum. The main indication for this operation was the rare condition of congenital cystic dilatation of the common duct; it might also be performed in cases of obstruction from pancreatitis or carcinoma of the pancreas where the gall-bladder was not available for cholecystenterostomy owing to disease or its previous removal. The operation was not a very satisfactory one; it caused angulation of the duct with stress on the suture line, and the opening, being large, involved a risk of the passage of duodenal contents into the duct with the consequent risk of infection of the latter.

3. *Reformation of the Common Duct* was called for when considerable segments of the duct had been excised for a growth or fibrous stricture, or for fistula resulting from surgical injury unrecognised at the time. In the latter cases the structures were much obscured by inflammatory changes, and the lower part of the duct was often practically obliterated. Attempt

had been made to form a new duct from an autogenous graft of fascia later, but these operations were difficult and a portion of the graft was likely to fail. Practically every case could be treated by either direct or indirect implantation of the upper end of the duct into the duodenum.

(*a*) *Direct Implantation*, first performed by Dr. Mayo wherever possible was the operation of choice; the upper end of the duct was brought down and anastomosed to an artificial opening in the duodenum. The opening must be so devised as to be valvular; this was accomplished in Mayo's operation by making a somewhat circular incision in the duodenum thus producing a flap-like formation, and in other cases by burying the duct obliquely in the duodenal wall for some distance. Such operations were naturally only available when the duodenum was mobile—that is, when the operation was a primary one. It would appear to be essential that the opening should be valvular to prevent an ascending cholangitis. When the duodenum was not sufficiently mobile a loop of jejunum brought through the transverse mesocolon might be employed, but such a loop was unsatisfactory by causing traction upon the anastomosis.

(*b*) *Indirect Implantation.* — Sullivan's original method was to wrap omentum round a rubber tube implanted into the duodenum at one end and into the duct at the other, in the hope that a fistulous track would be produced and the tube passed later. Such operations were often unsatisfactory. The tube, failing to be passed, might become encrusted with calculous deposit, or the fistulous track might become stenosed after the tube had been passed. These drawbacks were now overcome by using a flap cut from the anterior surface of the duodenum in place of omentum. The technique of this operation, which was described in considerable detail, was comparatively simple, and the operation was available even when large gaps had to be bridged. The new duct was valvular and was lined with duodenal mucosa accustomed to the passage of bile. The rubber tube, which was held in place by only one plain catgut suture, was usually passed within a fortnight. The flap operation could by a simple modification be employed for those cases where the common duct was dilated from obstruction by chronic pancreatitis or carcinoma of the head of the pancreas, a lateral opening being made in the duct and anastomosed by means of the flap to the duodenum.

The PRESIDENT remarked briefly on the extreme importance of care and a knowledge of pathological anatomy in the operation of cholecystectomy or any other operation in this region.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

METASTATIC GONORRHŒA.

A MEETING of this Society was held at the rooms of the Medical Society of London on June 29th, Dr. F. N. KAY MENZIES occupying the chair.

The discussion on the metastatic results of venereal disease, reported in THE LANCET last week, was concluded, the subject being dealt with from the aspects of affections of the eye, the skin, the cardiovascular system, and the kidney.

Mr. SYDNEY H. BROWNING and Mr. BASIL LANG dealt with

Gonococcal Affections of the Eye.

Mr. BROWNING based his contribution on his experience at Moorfields Eye Hospital during the last 14 years. Ten years ago, he said, gonococcal ophthalmia in newly-born infants was very common; to-day it was very rare, a remarkably sudden decrease occurring when, in 1920, there was extra supervision of and greater care by midwives. Most of the infants so suffering nowadays had a chemical irritation due to over-zeal, and this might be a seat of secondary infection by various pathogenic germs, conveyed, probably, by the family handkerchief. An enormous advantage in culture of the gonococcus was obtained by using Dr. P. P. Laidlaw's method of diminished oxygen tension, which he described. Vaccines he had not found of material benefit in any way to children with gonorrhœal ophthalmia. Despite appearances, patients must not be considered cured until the conjunctivæ were proved bacteriologically to be free of gonococci. In adults gonorrhœal ophthalmia usually resulted from an existing acute or subacute urethritis. Here, vaccine therapy in many cases diminished the frequency of ulceration. The urethra must be treated at the same time; and if only one eye was involved, the other must be protected. He did not know of a case in an adult in which the gonococcus had been recovered from either gonorrhœal conjunctivitis or irido-cyclitis. Pus existed in the conjunctiva in these conditions, but it had not been shown to contain organisms. They were probably toxic. As gonorrhœal iritis was a late sequel of gonorrhœa, it was not usually seen at first hand by the V.D. specialist, and it was generally treated as a purely local infection. He did not think it was set up by the presence of the gonococcus in the eye. Still, there was good reason for believing that the origin was gonorrhœal, for there was usually a history of gonorrhœa, there was a specific reaction to gonococcal vaccines, and a recurrence of the iritis followed prostatic and vesicular massage. Incidentally, he mentioned that he had neither seen nor heard of a case of gonorrhœal iritis in the female. Immediate vaccine therapy was indicated in all cases of gonorrhœal iritis, and it should be pushed to the extent of securing a considerable reaction in the eye. Detoxicated vaccines had not yielded any results in his hands.

Mr. BASIL LANG said there were three types of metastatic infections of the eye from gonorrhœa: iritis, scleritis, and choroiditis. The first and second were uncommon from this cause, and choroiditis without scleritis quite rare. Usually a joint affection preceded any of the three. The distinguishing feature of this iritis from other forms was a clear gelatinous exudate into the anterior chamber, and the iritis was always associated with congestion of the ciliary vessels, and easily elicited tenderness over the ciliary region. The scleritis was acute in onset, and there was pain with chemosis. The choroiditis was also very sudden in onset, and the vitreous early contained many "floaters." With regard to treatment of the iritis, the pupil must be kept dilated at all costs. The atropine for this purpose was best used dissolved in castor oil, or made into an ointment with yellow vaseline. Cocaine, adrenalin, and leeches should be tried, as all blanched the eye. Leeches quickly reduced the pain. After these had been applied, the patient should bathe the eye with hot boric lotion. If heat did not benefit, cold compresses could be tried. He had never seen glaucoma produced by acute iritis. Gonorrhœal scleritis was treated on similar lines to the iritis. As to the general treatment, the patient was best in bed, and the bowels should be kept well open. Recurring iritis might be due not to the gonococcus but to a streptococcus. Sometimes an autogenous streptococcal vaccine caused a rapid cure.

Gonorrhœal Affections of the Skin.

Dr. H. G. ADAMSON dealt with the subject from the standpoint of skin diseases. He said gonococcal metastatic skin eruptions must be understood to mean eruptions produced by gonococci carried to the skin by the blood-stream. He questioned, however, the existence of such eruptions; dermatologists had little, if any, practical experience of them. The statement originated in monographs written by a German—Buschke, and a Frenchman—Perrin, in 1900, and had been copied into books ever since. Audrey, however, a careful French observer, published a case which deserved attention, in which erythematous patches following fever and joint pains showed points of suppuration, which coalesced into an abscess, and the pus from this contained gonococci in abundance. Audrey suggested that the gonococcus should be looked for in other cases of erythema multiforme. A different eruption, seen in association with gonorrhœal infection, was keratodermia blenorrhagica. This consisted of conical, horny, or translucent-looking elevations, varying in size from that of a pea to an inch across, situated chiefly on hands and feet; they might encircle the nails, and occur on the nail-beds, resulting in the nail being either raised or cast off. Sometimes a peculiar balanitis was also present. In most cases it accompanied severe gonorrhœal arthritis, with recent urethritis. Most of these cases recovered spontaneously in the course of several months by the separation and fall of the horny matter. In cases of undoubted keratodermia blenorrhagica frequently the patient was found to have also had psoriasis, or a psoriasiform eruption. The lesions of keratodermia blenorrhagica were really heaped-up masses which could be pulled off, leaving a smooth, glazed surface; the process was not really a hyperkeratosis, but a parakeratosis, like that in psoriasis. The question arose whether in keratodermia blenorrhagica one was not dealing with severe psoriasis in a patient predisposed to gonorrhœa. He quoted cases which seemed to bear out this view. Possibly psoriasis might be due to a microbe related to the gonococcus.

Gonorrhœa and the Cardiovascular System.

Dr. R. A. **ROWLANDS** dealt with the subject in its relation to the cardiovascular system. He said Lacassagne, in 1872, considered that cardiac complications were very rare in gonorrhœa; but the endocardium and pericardium were attacked, particularly the latter. In 1895 Thayer and Blumer proved the existence of a gonococcal septicæmia, as well as an ulcerative endocarditis, due to the gonococcus alone. In 31 per cent. of Thayer's cases there was arthritis during the course of the illness; and in a series culled from literature it was present in 68 per cent. The symptoms were those of septicæmia. There was headache, lassitude, pain in the loin, and when of sudden onset it was ushered in with a rigor. There was also irregularly remittent or intermittent fever, associated with rigors and sweating. There was in addition rapidly developing secondary anæmia, which became more marked with the longer duration. In all cases there was a very marked leucocytosis. In two-thirds of the cases there were embolic phenomena in the skin, kidney, spleen, brain, lungs, or skeletal muscles. Renal infarction was shown in ten cases by hæmaturia, and in two cases there was a partial hemiplegia. Cutaneous hæmorrhages were present in six out of 11 cases. Acute or subacute nephritis was found in most of the cases. The average duration of the disease was nine and a half weeks, and in four cases there was a terminal mixed infection. The anatomical lesions were those of vegetative or ulcerative endocarditis. Mural endocarditis was present in eight out of 20 cases, while in four cases acute pericarditis existed. Dr. Rowlands proceeded to describe a number of cases, and gave the post-mortem findings in one or two fatal cases. It was not the rule to examine the hearts of patients when they first came suffering from gonorrhœa. A previous rheumatic endocarditis did not predispose to gonococcal disease of the endocardium, for gonorrhœa was quite as liable to attack a healthy valve.

Mr. **KENNETH WALKER** spoke on the subject in relation to the kidney. He said the gonococcus might be present unsuspected in the epididymis until a blow, by lowering the vitality of the part, enabled the activity of the organism to be revealed. Sometimes a pathologist would fail to find it on two occasions and succeed on a third, which would seem to show that the discharge of the organisms into the general circulation took place at odd times, the flooding of the blood-stream coinciding with rises of temperature. He believed the commonest portal of entry of the organisms into the blood-stream was the prostate. Gonococcal pyæmia showed a mortality, according to French authorities, of about 30 per cent. Apparently the vascular lesion was the fatal one. Considering how common was gonococcal infection of the lower urinary tract, it was surprising how seldom the kidneys were attacked. In many cases of so-called gonococcal pyelitis the trouble was found to be due to secondary organisms. Semens, in a search of the literature, was able to find only 25 cases of undoubted gonococcal infections of the kidney, and of these only 15 were purely gonococcal. A few of them seemed to be cases of an ascending infection. Gonococcal bacteriæmia seemed to be of fairly frequent occurrence. The most fatal lesion of gonococcal pyæmia was endocarditis.

Major A. T. **FROST** thought it likely that the reason very few cases of metastatic complications of gonorrhœa were seen in army practice was that special attention was paid to the prostate gland; every case was thoroughly examined, and the gland massaged; and the man was not allowed to leave the hospital until, by all the known tests, the prostate was normal. He had seen very successful results of treating keratodermia blenorrhagica by means of vaccines. That seemed to show that it was a toxæmia, especially as in that disease no one had found the organism under the skin. At Rochester Row the same good results as Mr. Browning's had not been experienced by the use of low oxygen tension. The governing factor seemed to be the hydrogen-ion concentration.

Dr. T. **ANWYL-DAVIES** spoke of a case in which, four days after marriage, the gonococcus was grown in pure culture from the cervix, which showed no sign of inflammation. The husband had acquired gonorrhœa six weeks previously. The woman attended because of an ankle lesion, which was almost suppurating. The condition cleared up under a course of vaccines. In another case repeated tests of the urethra and cervix failed to reveal gonococci in the pus, but after treatment had continued a month there was arthritis of the elbow. This was punctured, and pure gonococcus was obtained. The case cleared up with plugging and catheterisation of the uterus, and the use of vaccines.

Mr. **SYDNEY MACDONALD** said he regarded the vesicle as the chief port of entry of the gonococcus to the general system. Excising the vesicle seemed to be the only means of cutting off the source of infection; he did not think it could be drained. Sometimes sufferers from joint affections were found to have had gonorrhœa ten to 25 years previously.

MESSRS. Cassell and Co., Ltd., announce the forthcoming publication of the second (revised) edition of Choyce's System of Surgery.

THE University of London Press announce the forthcoming publication of the following: "Diseases of the Breast," by Mr. Willmott H. Evans; "Daydreams; a Study in Development," by Mr. G. H. Green, B.Sc.; "The Young Delinquent," the first of three volumes on the Sub-Normal School Child, by Dr. Cyril Burt; and "Talks on Psychotherapy," being the course of lectures recently delivered at King's College, University of London, by Dr. William Brown.

DONATIONS AND BEQUESTS.—The late Mr. Thomas Arnold Cash, of Highgate and Coventry, left by will, among other bequests, £2000 upon trust to enable his brother to carry on the work for the promotion of the Humane Slaughtering of Animals, £1000 to the Model Abattoir Society, £1000 to the Coventry Society for the Prevention of Cruelty to Animals, for investment for the maintenance of a whole-time inspector for Coventry and the surrounding district; £1000 to the Coventry and North Warwickshire Hospital; and £1000 to the Birmingham Cripples' Union for the establishment or support of a branch in Coventry. On the death of his wife he left £5000 to the Corporation of the City of Coventry for a public abattoir and cattle market.—By the will of the late Mr. Johann August Diederich Bornemann, of Lincoln, the testator left among bequests £1000 to the Lincoln County Hospital and £100 to the Lincoln General Dispensary.

Reviews and Notices of Books.

A TEXT-BOOK OF PHARMACOLOGY AND THERAPEUTICS.

By E. POULSSON, Professor of Pharmacology in the University of Christiania. English edition, edited by W. E. DIXON, M.A., M.D., F.R.S., Reader in Pharmacology and Assessor to the Regius Professor of Physic, Cambridge. London: William Heinemann (Medical Books), Ltd. 1923. With 31 illustrations. Pp. 519. 25*s.*

IN no branch of medical study is the text-book so important as in pharmacology, for it is this subject which receives the least attention in the race to cover the fields of all the medical sciences, and the lecturer's opportunities of interesting the student in it are few. Writers of pharmacological works have perhaps the most fascinating of all material at their disposal, but the text-book worthy of pharmacology is yet to be produced. It will not be content to assume the form of a work of reference which only those already well grounded in physiology and pathology can usefully read, but it will give an account of the physiological and pathological processes occurring in the different systems, and then discuss the modification of function by pharmacological means. Such a book, carefully written, might be lengthy, but it would be of very great interest to the student, and of enormous value in inculcating a scientific method of approach towards all medical problems.

The scope of the standard text-books of pharmacology in current use in this and other countries is much more limited. The plan usually adopted is to take each drug separately and detail its several actions, to provide, as it were, a catalogue without much cohesion. Prof. Poulsson has not departed from this general pattern, but within its limits his text-book is a very creditable production. Already well known on the continent, it makes its first appearance in English under the trustworthy editorship of Dr. W. E. Dixon. It is essentially a book for the medical student, condensing its matter to a point mid-way between the larger text-book of Cushny and the smaller manual by Dixon, and in general presentation of the subject having considerable resemblance to both. The translation has been well done, for the sentences always run smoothly, and a reasonable balance has been maintained between the size of the volume and the size of the type. The classification followed is that of Schmiedeberg, and the various agents are taken one by one in an order permitting of easy steps, their pharmacological and clinical effects being described. As is to be expected, much of the experimental groundwork done by English workers does not appear, but in the general conclusions about the manner in which different drugs act there is an astonishing measure of agreement with current English points of view. Mention is made of some of the newer therapeutic agents, such as sodium, potassium, bismuth tartrate for syphilis and insulin for diabetes; it is perhaps a pity that a fuller account of these is not given, and that there is no discussion of other new treatments, such as the use of quinidine in heart disease. It is indeed surprising to find the statement that of the 20 different cinchona alkaloids "only quinine is of any great medicinal importance," for the value of the others in the treatment of malaria is now well authenticated.

These are small points, however, and on the whole Prof. Poulsson's manual contains sound orthodox teaching, clearly set out, and should be greatly appreciated by students of medicine.

ANALYTICAL MICROSCOPY.

By T. E. WALLIS, B.Sc., F.I.C., Ph.C. London: E. Arnold. 1923. Pp. 149. 6*s.*

MR. T. E. Wallis's little handbook on Analytical Microscopy, although intended primarily for the analytical chemist and pharmacist, can be recommended for a place on the shelves of the medical microscopist. All too frequently he encounters in his preparations of pathological material foreign matters not easily recognisable as such. Unidentified structures of vegetable origin have before now figured as cancer parasites to the confusion of the weaker brethren. It is not too much to say that most of this nonsense would never have seen the light of day if the observers had even glanced through the extremely serviceable and well-chosen illustrations of this book. The essential addition of the magnification of every figure, which is a welcome and valuable feature, is too seldom carried out by other writers on the microscope. The directions for working methods are clear and crisp and many have a wider application than is modestly claimed for them in the preface.

HOW WE RESIST DISEASE.

An Introduction to Immunity. By JEAN BROADHURST, Ph.D., Assistant Professor of Biology, Teacher's College, Columbia University. London and Philadelphia: J. B. Lippincott Company. 1923. With 138 text figures and 4 coloured plates. Pp. 248. 10*s.* 6*d.*

THIS cheerful book is one of the publisher's series of nursing manuals. It is meant as a short introduction to immunity for those who already have some acquaintance with systematic bacteriology and is designed primarily for nurses and general science students whose course cannot include anything like the full instruction given to medical students. It is well and clearly written, abundantly illustrated, and remarkably cheap. In a short compass it gives a great deal of information, and any nurse or layman who was tolerably well acquainted with its contents would be able to talk about immunity with some facility. But whether they would know much about it is another matter. The book is quite a brilliant attempt to make the royal road. It may seem to have succeeded. But, of course, it really fails, and to pretend to any university student that he can know about immunity without sweat and tears is to cheat him of his education. As to nurses, the days are no doubt gone when Florence Nightingale said, "the strongest to the wash-tub," and if they really know all there is to be known about bed-comfort and all the arts of sympathetic kindness which have saved more lives than antisera, they will no doubt be the better for reading Dr. Broadhurst as an optional graduate course reserved for those who have learned their business. It is a book for some sisters, not for all probationers. The senior medical student who knows his Muir and Ritchie might read it with advantage; many of the points are put very well and some of the diagrams are excellent. And it can be heartily commended to practitioners who have got out of touch with modern practical serology. But as a student's manual it will not do; one might as well propose to substitute Sir Oliver Lodge's "Easy Mathematics" for Pendlebury, or Hall and Knight.

ANORMALE KINDER.

By Dr. L. SCHOLZ, Nervenarzt in Bremen. Third revised edition by Prof. Dr. ADALBERT GREGOR, Direktor der Fürsorge-erziehungsanstalt Flehingen in Baden. Berlin: S. Karger. 1922. Pp. 312. M.30.

WE reviewed the first edition of this book in 1912. Dr. Scholz fell in the war and another hand has revised and enlarged the monograph, notably in the direction of amplifying the sections on after-care and social service. According to the author, of every 200 German children three are feeble-minded, which gives a total of about 180,000 for the 12 millions of children of school age. Figures quoted from Switzerland give a percentage of 1·6, which is approximately the same. The handling of such numbers, medically and educationally, is a task calling for a body of helpers in numbers far beyond those already enlisted, and for adequate assistance from the State. A full description is furnished of the methods in vogue in institutions, families and special schools. As far as we are aware, Dr. Scholz's work has not appeared in English, yet it contains much which should appeal to a wider public.

Specific Reflexes.

Untersuchungen über die Eigenreflexe (Sehnenreflexe) menschlicher Muskeln. By PAUL HOFFMANN, Privatdocent für Physiologie in Wurzburg. Berlin: Julius Springer. 1922. With 38 illustrations. Pp. 106. 6s.

THIS little book contains in small compass much physiological information the clinical bearing of which must be of particular interest to the neurologist, who deals with reflexes daily. Dr. Hoffmann considers, justly, that the term tendon-reflex is misleading, and he prefers to substitute for it the expression "specific reflex," meaning thereby that each muscle of the body (this can obviously be demonstrated more easily in some than in others) has its own reflex—i.e., makes its response to the adequate stimulus. It is unnecessary for the clinician to load text-books with tables of reflexes; he need only select one or two as of practical value. All skeletal muscles have this property in common, that if their extent is abruptly lengthened by any mechanical device they respond, provided the tonus is sufficient, by a contraction, which is not a movement, but a necessary, partial, function of all voluntary movements. Its isolated appearance, as in reflex-testing, is meaningless, or, rather objectless. The specific nature of the reaction is fully investigated by Dr. Hoffmann mainly with the help of the newer methods such as the Einthoven galvanometer, and the phenomena of facilitation and inhibition are minutely described.

The Emotions.

By CARL GEORG LANGE (1834–1900), University of Copenhagen, and WILLIAM JAMES (1842–1910), Harvard University. Psychology Classics: a Series of Reprints and Translations. Edited by KNIGHT DUNLAP, Johns Hopkins University. Vol. I. Baltimore: Williams and Wilkins Company. 1922. Pp. 135. $4.

Dr. Knight Dunlap has undertaken a commendable task in editing a series of reprints and new translations of psychological classics, and the first volume will undoubtedly lay the student of psychology, philosophy, or physiology under a debt of obligation to him. It contains (1) a new version from the German text of Prof. Carl Lange's book "Ueber Gemuthsbewegungen" (1885), and (2) a reprint of Prof. James's article in *Mind* (1884), entitled "What is an Emotion?" together with the chapter on the emotions from his "Principles of Psychology." In the history of the subject the James–Lange theory has exercised a profound influence on contemporary and later workers, and while it may be that the hypothesis stands in need of revision, or of "softening," as the editor says, at any rate it should be fully understood by those who are inclined to discard it. All who are interested should make themselves familiar with the originals as now first presented in convenient and consecutive fashion.

Der Balken.

Eine Anatomische, Physiopathologische, und Klinische Studie. By Dr. G. MINGAZZINI, Professor of Nervous Disease in the Royal University of Rome. Berlin: Julius Springer. 1922. With 84 illustrations. Pp. 212.

Prof. Mingazzini's monograph on the corpus callosum provides a remarkably complete account, anatomical, pathological, and clinical, of the largest commissure in the brain, and embodies much valuable information gleaned from various papers scattered through the literature and not readily accessible to the student. Within recent years attention has been directed to the corpus callosum mainly from the point of view of transcortical disorders of function, such as apraxia and agnosia, and approximate localisation within it has been rendered possible by the labours of many neuropathologists. The experimentalist, also, has worked at its physiology. The monograph under review should at once find its place in the library of every neurologist, since no text-book deals with its subject-matter so adequately, nor has any previous similar contribution been so detailed or so informative.

A Compendium of Tuberculosis Therapy.

Handbuch der gesamten Tuberkulose-Therapie. Edited by Prof. Dr. med. ERNST LOEWENSTEIN. Vienna: Urban and Schwarzenberg. 1923. In two volumes. With 32 illustrations, some coloured. Pp. 1044.

THE first part of this bulky handbook is published in two volumes, and if the second part is as bulky as the first, it would be more accurate to describe this work as a library than as a handbook. In his foreword, printed at the end of these volumes, Prof. Loewenstein states that this work is the sequel to post-graduate courses given by himself—courses which whetted the appetite of his pupils for a systematic course of published lectures by well-known authorities. The work is addressed to general practitioners, whom Prof. Loewenstein would like to see converted wholesale into tuberculosis specialists. Only thus can the campaign against tuberculosis become effective; hospitals and sanatoriums are but stations on the consumptive's long journey, and he will fare well or ill according as the long distances between these rare stations are patrolled efficiently by the general practitioner. It is customary to speak of him as the "busy" general practitioner. The many to whom this adjective applies may be more than a little alarmed by these 1044 pages, with the promise of more to come. Fortunately the subject is well classified, and thus the first qualification of a useful work of reference is guaranteed.

The editor of a work like this, to which many specialists contribute, should be a good team-driver, with a discriminating sense of proportion and balance. In this connexion it is a pity that one of Prof. Loewenstein's team of 20 has got out of hand. Nearly half of this first volume (469 pages, to be exact) is devoted to diet in tuberculosis, and it is doubtful if even the general practitioner who is not busy will find time to digest this monograph. The other contributors have kept their contributions within more modest limits, and the value of their work has certainly not suffered from their parsimony of words. Naturally many of the authors hail from Vienna, but the general editor has given a cosmopolitan flavour to his work by the inclusion of contributors from Barcelona, Philadelphia, Berlin, and Göttingen. Though the work is mainly concerned with treatment, there is plenty of pathology and even pure physics, and the chapter on the physical, chemical, and biological foundations of treatment by radiation is highly technical. There is a dry, but instructive, chapter on the statistics of tuberculosis by Prof. L. Teleky, of Düsseldorf, and a long and interesting chapter is contributed by Prof. G. Liebermeister on tuberculosis of the blood-vessels. A chapter with the intriguing title, "Statistics of Sanatorium Results," must bring disappointment to the statistician, for analysis shows that the statistical support of this form of treatment is very unreliable. The author concludes that a better estimate of the value of this treatment can be formed by the clinical study, by an expert, of a large number of cases. Another chapter is devoted to tuberculosis in relation to pregnancy, and the author, Dr. Frischbier, is in favour of inducing abortion when pulmonary disease is progressive. But he is not reckless in this direction, and he gives the very useful advice that the pregnant patient should be kept under observation for a month in a sanatorium before the fate of the fœtus is settled. In favour of inducing abortion he points out that the infant mortality in this class of case is about 70 per cent., and that inducing abortion has a favourable effect on the patient in about the same percentage. The chapter on respiratory exercises in pulmonary tuberculosis will give pause to readers who regard such exercises as the most effective method of inducing auto-inoculation.

In spite of the intrinsic merit of many of the chapters it is an open question whether such a large work, addressed to the general practitioner, does not defeat its own object.

ALFRED YARROW: HIS LIFE AND WORK.

By ELEANOR C. BARNES (Lady Yarrow). London: Edward Arnold and Co. 1923. Pp. 328. 10s. 6d.

ONE of the seven wise men of Greece—namely, Solon—was of opinion that no man should be called happy while yet alive, for life is full of uncertainties. If, however, any man can be called happy while alive it is the subject of this memoir, for it is the story of a man who from small beginnings has built up a great business, has done nothing but good work, has won the affection of all who worked with him in whatever capacity, has rendered incalculable services to his country, and has accumulated a large fortune. This last item he would consider as the least of his benefits except in so far as it has enabled him to benefit his fellows in many ways, and in two particularly—namely, the Yarrow Convalescent Home for Children at Broadstairs and the gift of £25,000 towards the new out-patient room at the London Hospital. Sir Alfred Yarrow has reached his eighty-first year, and it must be with great content that he looks back over his past years. We congratulate Lady Yarrow upon her book, so simply and clearly written, giving a life-like picture of a man who was never satisfied in turning out any work but the best. How good the best was may be gathered from the records of the Yarrow destroyers during the war and also of the various classes of boats employed on the Tigris. As regards the latter operations Lady Yarrow records one delightful episode. The boats had been shipped in pieces and had to be assembled at Abadan. Mr. William Grant was in charge of the work and had to obtain workmen from all parts of the country, and consequently of varying nationalities, races, and creeds. He found that if a foreman wanted a tool, such as a hammer, he had to send two men for it, for if only one were sent "and if he were seized with a sudden desire to pray (falling on the ground for that purpose, in which devout occupation he must not be disturbed) the hammer might not appear for a considerable length of time." The British plumber is not, we imagine, hindered in getting tools which he has forgotten by "a sudden desire to pray," but it is a mark of the brotherhood of man that the same characteristics appear in the East as in the West. In relation to this matter, we may refer readers to Chapter XXX., which contains Yarrow's views on industrial problems, and is full of sound commonsense.

And here we must leave this fascinating book, but we cannot do so without wishing both its subject and its author many more years of useful happy life. Everyone will recollect the story of the Greek voter who voted against another citizen because he was tired of hearing him called "the Just." So as to spare Sir Alfred Yarrow from this fate we must recall one blot in his life's work, and that is, that so far as we can gather, he was the first to introduce steam launches on the upper Thames—a subject upon which the language of Eton and Oxford is comparable to that of the English army in Flanders in the eighteenth century. We will only add that this book ought to be in the hands of every boy, not only those who are going to be engineers, for it is a handbook to patience, perseverance, honest output, and how to spend money when it has been made.

JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES. Vol. XX. April–June.—Mr. T. B. Layton contributes a paper on the Treatment of Acute Otitis Media in Children, in which he points out that this treatment is one which should be carried out in nearly every case by the general practitioner. The patient should be kept at rest in bed, while local treatment consists in the incision of the drumhead at the right moment. Mr. Layton maintains that it should be the aim of every practitioner never to allow a drumhead to rupture spontaneously, to look upon an inflamed ear, which under his observation has gone on untouched to the stage of discharge, as something of a disgrace to himself, just as he would consider to be so a case of acute appendicitis which in similar circumstances had gone on to acute peritonitis. As it is important that nothing should prevent a good view of the drumhead being obtained, hot fomentations, which cause the superficial epithelium to swell up and entangle any bits of cerumen, should never be used, but pain should be relieved by application of dry heat to the ear and side of the head by a hot-water bottle and pad of wool, and by the installation of antiseptic drops. The drumhead should be incised as soon as it is seen to be bulged, the incision being made deliberately under an anæsthetic. In the subsequent treatment of the case the practitioner must watch carefully for signs of mastoiditis.—Dr. F. Parkes Weber contributes a paper entitled The Nature of Banti's Disease: Its Differentiation from Other Types of Splenomegaly and its Relation to "Idiopathic" Non-Alcoholic Progressive Hepatic Cirrhosis in Children and Young Persons.—In a paper on the Classification of Blood Diseases in Childhood, Dr. Gordon Ward has drawn up a new classification founded on a mixed anatomical and pathological basis. —Dr. R. Miller reports a case of cœliac disease showing symptoms of megacolon, with autopsy, his object being, first, to establish that cœliac disease may give rise to distension of the colon sufficient to cause visible colonic peristalsis, and, secondly, to confirm his view that cœliac disease is a digestive fault, and not an organic disease.—In a paper entitled On Localised Peritonitis Due to Intestinal Perforation in Paratyphoid Fever: Report of a Case, Mr. A. E. Mortimer Woolf states that perforation in paratyphoid fever is uncommon in civil practice, though during the war hæmorrhage and perforation were almost as frequent in paratyphoid as in typhoid. When perforation occurs in typhoid or paratyphoid, general peritonitis nearly always takes place. Although there are a few instances on record of localised peritoneal abscess in typhoid fever, the writer has been unable to find any previous examples occurring in either paratyphoid A or B. The case here reported was in a boy, aged 15, who developed acute abdominal pain on the fifteenth day of an attack of paratyphoid B. At operation a perforation was found in the lower end of the ileum walled off from the general peritoneal cavity by the great omentum. The perforation was closed, and recovery was uneventful.—In a paper on the Meningeal Form of Typhus in Children, MM. Gratzosky, Stroë, and Coccias, of Bucharest, remark that typhus in children occasionally assumes a meningeal form, of which they report three examples in patients aged 2, 3, and 7 years respectively. The meningeal symptoms consisted in strabismus, inequality of the pupils, nuchal rigidity, exaggerated reflexes, and positive Kernig and Brudzinski signs. On lumbar puncture a clear cerebro-spinal fluid was obtained under hypertension, containing abundant lymphocytes with a few red cells and polymorphonuclear leucocytes. One case was fatal, and the autopsy showed meningeal infiltration and a large quantity of cerebro-spinal fluid slightly blood-stained in character. The other two children recovered in nine and ten days respectively.—The abstracts from current literature are devoted to alimentary diseases and oto-rhino-laryngology.

THE LANCET.

LONDON: SATURDAY, JULY 7, 1923.

HOUSE INFECTION.

MUCH interest has been excited by the publication of Mr. Justice McCARDIE's reserved judgment in the case of COLLINS *v.* HOPKINS, the details of which are summarised on p. 34. His Lordship ruled that it was the obvious duty of a person, in whose house there has been recent infectious disease, to disinfect it in the most complete manner open to him, before letting it furnished. In his reading of the law a warranty is implied in any contract on the lessor's part that the premises are reasonably fit for habitation, including freedom from the risk of infectious disease, irrespective of whether the subject was mentioned between him and his prospective tenant or not. The law does not lay upon the lessor the obligation to consider the fads of nervous persons unreasonably afraid of infection where no danger exists. Nevertheless, if the lessor wishes to avoid trouble, he will be frank in mentioning any disease likely to cause alarm, and in giving full information as to the steps he has taken to remove any source of infection. We do not propose to comment in detail upon the many divergences in statement and in opinion which arose in the hearing of this very important case. Mr. Justice McCARDIE accepted as a fact that the house was left in a dirty condition, and his judgment was definitely based upon this premiss. Of course, if the house was dirty all the rest follows, for domestic dirt affords a nidus for the development of bacteria of all kinds, and no one should hand on the tenancy of dirty dwelling-rooms. We have a feeling that more might have been made by the defence of the preparations actually made for the tenant's incoming. There were no hangings but casement curtains, and these were washed; a solution of lysol was used for washing the floors; bed-clothes were sent to the laundry as well as the loose covers of furniture, and new covers were made for the cushions. But over and above this, there was the assurance on the part of the medical attendants that the case was not one with pronounced symptoms of advanced disease and that, although tubercle bacilli were present in the expectoration, the patient was sanatorium-trained, and meticulously careful in observing the instructions he received to prevent the spread of infection. The omission of notification to the local medical officer of health was indeed an unfortunate oversight, but the omission to fumigate the premises, we understand, was deliberate, in view of the care taken by the patient, and in view of the fact that he spent his time on the balcony and not in the rooms.

But although in this particular instance, and for the reasons stated, the case went against the defendant, that part of His Lordship's judgment which merits the closest attention is his statement that if the patient were properly trained as to his habits, if he carried out his medical instructions, and if full regard was paid to ventilation, sunlight, cleanliness, removal of dust and dirt, and the like, then the risk of infection might not be serious even to those who resided with him. Still less was the risk, he went on, to those who entered the house after the patient had left and if proper methods of disinfection had been adopted. We are grateful to the learned judge for thus setting out clearly the essential factors in the conveyance of infectious disease from one person to another. Only in regard to terminal disinfection would the modern hygienist place the emphasis differently. At a recent congress of the Royal Sanitary Institute, Dr. T. W. NAYLOR BARLOW, the President-elect of the Society of Medical Officers of Health, traversed the whole notion of the potency of present methods; he went so far as to say that all house disinfection might safely be scrapped. Without denying the possibility of transmitting disease by means of inanimate objects, he regarded books, the walls of rooms, and such like, as of no account as factors in the spread of disease, logically adding that the so-called disinfection of rooms by gas is futile and unscientific. Conviction is indeed growing, not in this country alone, that the living breathing human being is the only real danger. We recently quoted the decree of the Prussian Ministry of Health, the essence of which is to organise bedside disinfection during the whole course of a patient's illness in such a way as to make a final disinfection of secondary importance or, indeed, altogether superfluous. It is perpetuation of the chronic carrier to which professional and public attention alike should be directed, and, while gaseous disinfection by formalin and sulphur fumigations may be done, this sanitary ritual should not lead to neglect of the weightier matters of the law of personal hygiene, soap and elbow-grease, sunshine and ventilation.

THE SMALL-POX MENACE.

THE Minister of Health, in his opening statement in Committee on Supply in the House of Commons on June 28th, alluded to the present situation in regard to small-pox as distinctly serious, and regarded it as his duty to speak plainly. Whereas 20 years ago 75 per cent. of young children were vaccinated, to-day the percentage was only 38, and the country was faced with the possibility of the outbreak of a great epidemic which would be dangerous to health and even perhaps to life, besides inflicting injury upon the commerce of the country. The Ministry, he said, was watching the situation closely, and he emphasised as strongly as he could that the one sure protection against small-pox was vaccination, and that those who refused, or incited others to refuse it, were taking upon themselves a very grave responsibility. Up to June 16th 955 cases of small-pox had been brought to his notice, a number nearly as great as the total notifications of last year. Among those who had had experience of the actual disease, there had, he thought, been no doubt as to the nature of the recent cases. Although mild, the fact must not be lost sight of that the disease, which began in a mild form, might presently develop into something very much more serious. Mr. NEVILLE CHAMBERLAIN's words may be read in our Parliamentary Intelligence column.

The situation in Gloucester is reminiscent of the early days of public health administration, before there was a general recognition on the part of the community that health was a first charge on their time and interest, a basis on which alone the fabric of civilised life could be firmly built. Something has occurred in Gloucester to interrupt the orderly course of notification, isolation, and protection of contacts which has become the token of enlightened municipal action throughout most civilised countries. Expression has been given with more or less emphasis to three different shades of thought. Some of those prominent in civic life have held that, whatever the nature of the infectious exanthem prevalent in the town, nothing should be done about it in a public way, in order not to spoil the trading facilities and other amenities of the place—a natural but not very long-sighted form of local patriotism. Another section has regarded the diagnosis of chicken-pox almost in the nature of an article of faith not amenable to disproof by ordinary scientific criteria; for a considerable number of cases notified as chicken-pox, actually 31 in the week ending June 23rd, have been rediagnosed as small-pox by medical officers of the Ministry of Health and of the Metropolitan Asylums Board, whose knowledge as experts would receive immediate acceptance in a calm atmosphere. Difficulty seems to have arisen in regard to the distinction between chicken-pox and small-pox, largely owing to insufficient stress being laid on the distribution and simultaneous appearance of the rash and too much importance on the presence of constitutional symptoms; for, as we have already noted, and are glad still to be able to note, there has, so far, not been a single fatal case this year among all the notified cases of small-pox. This admirable mildness of the disease it is which has encouraged still another local view—namely, that the disease is small-pox, but that it does not matter, the mildness being such as to render the outbreak unimportant from a public health point of view, making it therefore unnecessary to impose limitations on personal liberty in connexion with it. We are glad to think that there is no body of medical opinion included in the first and third groups which we have mentioned, and that the doubt in regard to the diagnosis is honest doubt, bred of the lack of experience in seeing actual cases of small-pox, which is the heritage of the last two generations of medical men. Dr. W. McC. WANKLYN spoke very appropriately to Guy's medical students last week on this alleged inability of the medical profession to diagnose small-pox, and he laid before them the results of the consultative system of small-pox diagnosis in London and some solid proof of what this system of diagnosis has effected. It is something for which humanity may be thankful that one of the worst of infectious plagues betrays itself early by a characteristic skin eruption which it is not—to use the phrasing of the National Health Insurance Act—beyond the ability of the practitioner of ordinary competence and skill to discover.

◆

THE NATIONAL PHYSICAL LABORATORY.

AT the invitation of the President of the Royal Society a large company gathered at Teddington last week to view the various departments of the National Physical Laboratory. The opportunity of seeing the research and testing departments in full working order and of meeting experts in every branch of physical science, which the occasion afforded, was widely appreciated, and the spacious department of aero-dynamics, with its huge wind tunnels, formed a pleasant setting for the reception.

Among the many branches of science flourishing at the laboratory there is, perhaps, none so interesting from the medical point of view as that of radiology. The recommendations of the X Ray and Radium Protection Committee for the better protection and general improvement of the working conditions of X ray operators have resulted in a large number of X ray materials being submitted for test to this department. A report of the work has been made by Dr. G. W. C. KAYE and Dr. E. A. OWEN. It contains interesting data concerning the protection afforded by such substances as sheet lead, lead-impregnated rubber, lead glass, and barium-sulphate plasters. The lead equivalent—that is, the thickness of lead equivalent in absorption power to unit thickness of the material—has been determined, and the figures given in the report will be of great convenience to radiologists. Of the many interesting comparisons given the following may be cited. The lead equivalent of a 12-in. solid concrete floor is about 3 mm. The masses of a steel and a lead plate which afford equal protection against X rays excited by 100,000 volts are in the ratio of 4 to 1. Different makes of lead rubber are found to differ by as much as 100 per cent. in protective value. Among the substances used for tube boxes sheet lead appears to be the lightest protective material to use, lead rubber being anything from 5 to 25 per cent. heavier. The open lead glass bowl, commonly used with X ray tubes, is criticised by the authors, who state: "In our experience, where this type of shield is alone employed, it is often possible to take a radiograph in any part of a room where a tube is working." Concurrently with this research on X ray protection the department has carried out investigations on the intensity of X rays emitted by Coolidge and gas tubes when operated by various types of high-tension generator. The work has shown that the intensity of the radiation emitted by an X ray tube is not in all cases proportional to the mean current passing through the tube, when the applied voltage is kept constant. Further, the investigators are led to state that: "Considerations of voltage and current wave-forms point to the conclusion that for a given voltage, and when the maximum current is in phase with the maximum voltage, the intensity of radiation emitted by an X ray tube, whether of the gas or of the hot cathode type, is roughly proportional to the maximum or peak current passing through the tube. This is true both for coil and transformer discharges." The radiology department is fully alive to the increasing application of higher voltages in medicine and in the study of metallic structures, as is shown by recent acquisition of a 200 kilo volt machine. Doubtless many of the problems involved in the practice of deep therapy will receive due attention at the hands of the director and his assistants. The department of sound is growing, and among the exhibits many were of medical interest—in particular an apparatus for the production of sounds of constant intensity and telephonic methods for the measurement of sound intensity. Certain workers in this field claim that variations of intensity of one million fold can be detected by the ear, and further by the use of these methods it can be demonstrated that the ear is incapable of detecting a 10 per cent. change in the intensity of sound. The research in this direction contemplated by the department will be awaited with interest, and might eventually be applicable to stethoscopy. In the multitude of routine tests which are carried out in the various sections there is evidence in all directions of the ingenuity and thought expended on the minutest details of even the simplest physical determinations. For example, in tests made upon the clinical thermometer, despite the fact that less than 2 per cent. of the number received are rejected, each thermometer is tested at four different temperatures between 95° and 110° F., its readings at these points being compared with a standard thermometer. The comparison is carried out in an electrically heated water thermostat, in which the water is kept in very rapid circulation. After the comparison has been made for any one temperature, the water is raised in temperature a further two-tenths of a degree, and readings of the thermometers are again taken to ensure that they are responsive to slight temperature changes. At the present time about 1200 thermometers are tested daily in this manner.

Many fascinating exhibits were displayed by the optics division. The colour effects obtained with the Nutting colorimeter were as pleasing as the methods for measuring the radii of curvature of microscope objectives were ingenious. The polarimetric and saccharimetric equipment, together with the apparatus for lens testing, was particularly attractive. Though in three fascinating hours only a small part of the activities of the laboratory could be witnessed, it was possible to estimate the magnitude of the work efficiently dealt with. In the National Physical Laboratory the nation has an asset of incalculable value.

A SPA FOR THE T.B.M.

HARROGATE is making a push to become the place of healthy resort for the tired business man, that ill-defined but frequent product of our present-day city life. With its pleasant subalpine situation and its abundant facilities for the application of the healing virtues of waters and sunshine and fresh air, it is not unreasonable to suppose that the early stages of this real and destructive fatigue may be treated with success. Common experience, indeed, points in this direction, and medicine is primarily concerned with selecting the appropriate cases and eliminating those in which there is already the foundation of serious organic disease. For this Harrogate is well equipped, for it has clinical facilities which can easily be turned into team-work and pathological facilities to detect the early stages of organic malady during a period of time devoted to rest and recreation. Nor does Harrogate cater only for those of abundant means, for, through the Royal Bath Hospital, which has a considerable endowment and is largely supported by the more wealthy visitors, pass every year 2000 or more patients from all parts of England, and arrangements have been made by the local medical profession for the complete examination of cases of moderate means at an inclusive fee. A new Pullman car service has been inaugurated bringing the bracing northern spa within easy reach of comfortable travel from London and, contrary to foreign practice, two-thirds of the train is put at the disposal of modest purses.

INDEX TO "THE LANCET," VOL. I., 1923.

THE Index and Title-page to Vol. I., 1923, which was completed with the issue of June 30th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

SMALL-POX IN ENGLAND AND WALES.—During the week ending June 23rd 141 cases of small-pox were notified in England and Wales, the distribution being as follows: Derbyshire 12 (Alfreton 1, Belper 1, Heanor 4, Long Eaton 5, Clown R.D. 1): Durham 1 (Stockton-on-Tees); Gloucestershire 90 (Gloucester 79, including 31 cases notified as chicken-pox but rediagnosed as small-pox, Cheltenham 1, Stroud 2, Westbury-on-Severn 1, East Dean R.D. 4, Gloucester R.D. 3); Herefordshire 1 (Hereford): Nottinghamshire 21 (Kirkby-in-Ashfield 6, Warsop 15); Warwickshire 1 (Birmingham); Worcestershire 1 (Martley R.D.); Yorks North Riding 1 (Middlesbrough); Yorks West Riding 12 (Bentley-with-Arksay 2, Doncaster R.D. 10); Monmouthshire 1 (Risca).

Annotations.

"Ne quid nimis."

THE POSTPONED BIRTHDAY HONOURS.

LAST week-end was published the list of honours, conferred on the occasion of the King's birthday, announcement of which was postponed on account of the change in Prime Minister. A baronetcy has been conferred upon Sir Anthony Bowlby, K.C.B., K.C.M.G., K.C.V.O., President of the Royal College of Surgeons of England, and knighthoods upon Dr. George Francis Blacker, C.B.E., Dean of University College Hospital Medical School, and on Lieut.-Colonel Ewen John Maclean, chairman of the Consultative Council of the Welsh Board of Health. A Commandership of the Order of the British Empire has been conferred upon Lieut.-Colonel John Southey Bostock, R.A.M.C., Director of Medical Services of the Ministry of Pensions. To these gentlemen we offer hearty congratulations in the name of the medical profession. Other names in the list familiar to medicine are those of Sir William Plender, who has done excellent work in connexion with the National Health Insurance Act and who becomes a baronet, Mr. Walter Schroder, coroner for Central London, who becomes a Knight Commander of the British Empire, the Rev. Canon Frederick Charles Davies, vice-chairman of the Consultative Council of National Health Insurance, Mr. Walter Davies, chairman of the Manchester Hospitals Voluntary Committee, and Mr. Ernest Tom Neathercoat, President of the Pharmaceutical Society (for work in connexion with the Dangerous Drug Regulations), who become Commanders of the Order of the British Empire.

TUBERCULOSIS IN CHILDHOOD.

IN the July number of *Tubercle* there are several original articles and reviews dealing with tuberculosis in childhood. It has been said that if the problem of tuberculosis in childhood were solved, the problem of tuberculosis in the adult would practically cease to exist. In a paper by Dr. C. D. S. Agassiz and Dr. S. Roodhouse Gloyne an account is given of investigations undertaken with a view to determining whether or not the tubercle bacillus can be detected in the blood-stream in children at or about the time of the primary infection. In the cases chosen for this investigation the signs varied from those of slight involvement of the lymphatic glands to those of disease of the peritoneum or lungs. In the control cases the diagnosis of pulmonary tuberculosis was supported by extensive physical signs and the finding of tubercle bacilli in the sputum. From 1·5 to 10 c.cm. of blood were drawn from a vein, were mixed with a 1·5 per cent. solution of sodium citrate, and were in each case injected into two guinea-pigs. In no case did they develop tuberculosis, although blood obtained from these patients was drawn off both during apyrexial and pyrexial periods. It would thus appear that infection of the blood-stream by tubercle bacilli in children suffering from tuberculosis is not easily demonstrable by the method described, and the following alternative conclusions are drawn: That (*a*) the number of bacilli circulating in the blood is too small to be thus demonstrated, (*b*) they are discharged into the blood-stream only at intervals, or (*c*) extension of the disease takes place by some other route, such as the lymphatic system. A paper by Prof. P. Bull, of Christiania, contains a tale of an instructive mistake. A boy, aged 3, was supposed to be suffering from malignant disease of one testicle and metastases in the abdominal cavity. Laparotomy revealed no free peritoneal cavity; wherever he explored, Prof. Bull only found a curious greyish substance which seemed to have permeated the peritoneum, omentum, and neighbouring structures. Still thinking that the case was one of malignant disease, and therefore practically hopeless, he thrust radium tubes, without lead filters, into this greyish mass in various directions, the total dose of radium being 11 cgm. A week later the signs and symptoms of severe abdominal disease had vanished, and the child lived to die several months later of acute middle-ear disease. The necropsy showed extensive healing of tuberculosis in the peritoneal cavity and elsewhere. Among the reviews of original papers on tuberculosis in childhood there is one in which the value of a single Pirquet test is shown to be very untrustworthy. Of 800 children thus tested only 537 gave a positive reaction to the first Pirquet test with old tuberculin. Of the remaining 263 cases as many as 170, or 64·6 per cent., gave a positive tuberculin reaction either to a second Pirquet test or to the intracutaneous injection of old tuberculin in varying strengths.

FAITH AND PRACTICE.

IT is always rather difficult for a nonconformist of any complexion to understand the principles of the true faith, and when the *Homœopathic World* (No. 690, June, 1923) says that THE LANCET has "acknowledged the truth of the homœopathic principle," it is interesting to wonder to which or what principle assent has been given. Is it the original doctrine that *similia similibus curantur?* Or is it the more modern development which claims that drugs are effective in dilutions which would not contain a single molecule of the original active agent? Or is it the attribution of natures and qualities and emotions to plants which can be apprehended and used only by those in spiritual communion with the sources of drugs? It would be as difficult for the orthodox medical practitioner to draw up his creed of allopathy. Upon some of the clauses in both cases there would, we imagine, be insoluble differences of belief. But does this greatly matter when there is so much that is plain and fundamental from which no one will dissent? *In certis unitas, in dubiis libertas, in omnibus charitas.* No cult of medical men could have a better motto. And if it is followed in practice—and the more unconsciously the better—there is not much need to embark on the dangerous sea of putting down on paper what each group believes. They can all meet on the common ground of sincere humane and skilful work.

THE REGISTRATION OF DISEASE.

HOSPITAL statistics run largely to waste. This is, we think, the main lesson of a very interesting discussion on the Registration of Disease, opened by Dr. Reginald Dudfield at a meeting of the Royal Statistical Society last March,[1] and now reprinted. In his opening remarks at this discussion Dr. Dudfield pleaded for a utilisation of the records of sickness which accumulate in our general hospitals and other institutions for the treatment of disease. "It is a common experience," he said, "to read reports by different workers, dealing apparently with similar material, diametrically contradictory to each other." What is needed is the bringing together of the data derivable from all institutions, the collation and analysis of such data by a central body of statisticians who are not only statisticians but medical men of ripe judgment, well versed in the problems of public health. Other medical statisticians, Dr. T. H. C. Stevenson and Dr. Major Greenwood, and such eminent experts in public health matters as Sir William Hamer and Dr. John McVail, were in sympathy with Dr. Dudfield's general contentions. Dr. Stevenson pointed out that, even without drastic reform of the present system, some improvements might be effected. He instanced the emendation of the law required to secure knowledge of the sex and age distribution of cases of infectious disease, and suggested that a very good indication of the social class of each decedent would be afforded by a mere record of the number of rooms in the tenement occupied by the family. Dr. Greenwood dwelt upon the importance of a proper exploitation of hospital statistics, supplemented by a system of following up cases, in the study of the prognosis after operative or other treatment of malignant disease. Dr. Hamer advised Dr. Dudfield "in addition to trying to get more out of his Poor-law and health statistics" to try "to persuade the hospital authorities to introduce the study of disease as a mass phenomenon to their medical students." The medical profession as a whole will, we think, be in sympathy with Dr. Dudfield's ideas. Without doubt the economic and administrative difficulties of any centralisation of records are great, but the fact remains —and it is worth repeating and italicising—that, to a large extent, hospital experience *as a statistical datum* runs to waste. Of course, its value as such is only secondary, the highest use for hospital experience is its incorporation in the minds and practice of each generation of physicians and surgeons. But there is no opposition between these purposes. Sir William Osler could not be accused of having underrated the practical element in medical education, but, in his text-book, he employed the statistical method more fully and frequently than any other physician of his time. Dr. Dudfield's proposals would have had the full approval of that great physician.

A MILK-BORNE EPIDEMIC OF GASTRO-ENTERITIS.

A RECENT epidemic of milk-borne gastro-enteritis in Denmark has been the subject of instructive investigations by Dr. A. Christensen and Veterinary Surgeon P. Grinsted,[1] who claim that for the first time (with the possible exception of Dr. K. F. Meyer's case reported in the *Journal of Infectious Diseases* for 1916) proof positive has been found of a typical bovine paracoli infection being conveyed by cow's milk to man. The epidemic in question broke out on Oct. 11th, 1922, in a large hospital. Thirty-nine of the staff and 56 of the patients were seized with general malaise, fever, abdominal pain, nausea, headache, vomiting, and diarrhœa. In two cases there was an outbreak of herpes on the upper lip, and in one case there was partial loss of consciousness for 24 hours. None of the patients died, and no new cases occurred after the first outbreak. The incubation period was evidently very short, as was also the period during which the disease was contracted; for among the patients there was one who had been admitted to hospital for some other disease only the day before the outbreak occurred, and none of the persons admitted to hospital on the morning of the outbreak developed gastro-enteritis. All the patients had taken unboiled milk, and an inspection of the sources of the milk-supply led to the discovery that at a small farm one of the 13 cows in milk had fallen ill on Oct. 9th. Next day it had been very ill, with offensive diarrhœa and a temperature of 40° C. The cow died in the night of the 11th and 12th, but the milk yielded on the 9th had not been thrown away, although the cow's udder was œdematous. The necropsy on the cow showed definite signs of septicæmia, the spleen being gigantic and the liver and mucous lining of the small intestine showing acute inflammatory changes. Sections of the udder showed early mastitis which was evidently secondary to the enteritis and septicæmia. Numerous Gram-negative short bacilli, identified as bovine paracoli bacilli, were found in the spleen and secretion from the udder. A pure culture of the same bacilli was obtained from the fæces of two of the patients, and agglutination tests of the sera of 31 patients on the ninth to the twelfth day of the disease left little doubt as to the relation of the germs found in the cow to the epidemic in man. There is a disease in cattle, known in Denmark as "paracoli bacillosis," from which calves often suffer, but to which full-grown cattle are usually immune. It may be that this comparative immunity of full-grown cattle to paracoli bacilli explains the rarity with which human beings seem to contract this form of gastro-enteritis. But it is conceivable that this rarity is more apparent than real, and that were agglutination tests to be carried out more frequently in epidemics of this kind, bovine paracoli bacilli would often be convicted. The moral of this episode is not far to seek. Were farmers to be systematically taught the risks of keeping the milk of sick cattle, they would not be tempted to follow the penny-wise-pound-foolish policy of mixing infected with pure milk.

A POST-GRADUATE COURSE ON ALPINE THERAPEUTICS.

WE have received the announcement of a course of vacation lectures on Tuberculosis in the Alpine Climate to be held at the Research Institute in Davos from the 19th to 26th of the coming August. This Institute, in regard to which we were able to give some preliminary details last autumn, has now materialised as far as its physiological section is concerned, under the management of Prof. A. Loewy, who was for long one of a group of collaborators with Prof. Zuntz in respiratory problems. The bacteriological section of the Institute is also ready for occupation, and it is hoped to place this in the charge of an expert, when the expected help from the Swiss Confederation comes in after the Tuberculosis Bill has become law. At present the joint sponsors of the Institute are the medical associations in Davos, Arosa, and the Grisons, the Swiss Association of Naturalists, the Swiss Red Cross, and the Swiss Association for Balneology and Climatology. The meteorological observatory, under the direction of Prof. C. Dorno, is in close association with the Institute, and it is therefore possible to study clinical problems from the varied standpoint of meteorology, physiology, and pathology. Voluntary studentships at the Institute will be open to a certain number of workers. The principal items of study during the vacation course will be the pathology of tuberculosis, modern views on immune biology, general and special diagnosis with exhibition of cases, X ray and laboratory demonstrations, pneumothorax and other surgical treatment of pulmonary disease, and the application of altitude treatment to diseases other than tuberculosis, such as asthma, diabetes, and malaria. Forenoons will be devoted to lectures and demonstrations, while afternoons will remain free for visits and excursions. The course is free, the lectures being delivered in French or German. Board and lodging is offered at an inclusive charge of 10 francs a day, to those attending the course. Further information will be given on application to the Scientific Research Institute, Davos, Switzerland.

THE AGENT PRODUCING SYMPTOMS IN EXOPHTHALMIC GOITRE.

THE symptoms of exophthalmic goitre are usually attributed to the presence in the blood of an abnormal amount of the active principle of the thyroid secretion —a supposition supported by the known fact that administration of an excessive amount of thyroid substance to normal individuals is followed by symptoms which are similar to those characterising this disease. In order to ascertain whether thyroid secretion circulating in the blood is the agent producing the characteristic symptoms, certain tests have been applied by Sir E. Sharpey-Schafer[1] to the blood of persons suffering from exophthalmic goitre and to that of normal individuals as controls. The "intestinal test" depends on the fact that the addition of a small amount of extract of thyroid to Ringer's fluid in which a strip of cat intestine is suspended causes an increase both in the rhythmic movements of the strip and in its tone. The test is not very delicate, nor indeed specific, since many other substances may produce a similar action. The serum of normal blood contains a substance which produces marked augmentation and acceleration of the contractions of an isolated strip of cat's ileum; the effect of serum from cases of exophthalmic goitre is, however, far greater than that of the serum of normal blood. Thyroid extract also produces augmentation and acceleration of the contractions of the intestinal strip, but the action of thyroid extract is relatively slight compared with that even of normal serum, and the specific autacoid of the thyroid (thyroxin) has no effect in the intestinal strip. Moreover, neither normal blood nor exophthalmic blood, when fed to tadpoles, have any influence upon their metamorphoses, though thyroxin markedly accelerates the metamorphosis of frog tadpoles (tadpole test). These experiments, therefore, lend no support to the view that normal thyroid secretion containing thyroxin is poured into the blood in appreciably increased amount in exophthalmic goitre. Nor do they support the view that the symptoms of the disease are due to the presence of an abnormal amount of free adrenalin in the blood, since if this were the case, the contractions of the intestinal strip would tend to be inhibited instead of being augmented.

TWIN TUBAL PREGNANCY.

ACCORDING to Mr. Leslie B. Arey,[1] of the Anatomical Laboratory, Northwestern University Medical School, Chicago, the commonest plural pregnancy which involves the uterine tubes is the combined tubo-uterine type. One hundred and nineteen cases were collected by Weibel in 1905, although probably some of them were merely presumptive and not all were twins. Plural gestation in the same tube, of which 37 genuine cases were collected by Hardouin in 1919, is next most frequent, while bilateral tubal pregnancies are rarest of all, there being less than a dozen on record. A study of the literature shows that tubal pregnancy, whether single or twin, tends to occur in women who are older by 4½ years (31·0 years) than the average age for motherhood (26·5 years). Two groups of cases may be distinguished. The first which forms three-quarters of the total consists of women who have borne children, but without recent pregnancies, and nearly one-half are multiparæ, many having had abortions. The remaining fourth consists of women who have been married a relatively long time, on an average six years, but without becoming pregnant. The explanation of this sterile interval is to be found in tubal inflammation, which is the chief factor in tubal gestation. An inflammatory process may prevent pregnancy for a variable period either by mechanically blocking fertilisation or by causing young ova to disintegrate, and on subsidence of the inflammation the tube becomes a possible nidus for the growing ovum. Rupture occurs in 58 per cent. of all cases of single tubal pregnancy. It is most frequent in tubes containing normal embryos, less common in tubes in which the embryos are pathological, and rarest in those without embryos but containing degenerated ova, so that a growing normal embryo is a special menace to the mother. Eighty per cent. of the recorded specimens of monochorionic tubal twins have ruptured, but the writer regards this figure as too high, because unruptured specimens with degenerated embryos necessarily escape recognition. The average time of rupture in single tubal pregnancy in 25 cases was at 7·7 weeks, as compared with 10·3 weeks in a series of 28 cases of twin tubal pregnancy, but it is probable that the unusual feature of twinning leads to a more representative collection of the older specimens than in single gestations, so that the later date in the twin group is not really significant. The symptoms of twin tubal pregnancy are identical with the classical picture of ordinary tubal gestation. In 9 out of 36 cases with adequate menstrual histories the embryos were of such size as to indicate that there had been one and in a few cases more than one menstrual period before pregnancy had begun. The condition has radium tubes, without lead filters, into this greyish mass in various directions, the total dose of radium being 11 cgm. A week later the signs and symptoms of severe abdominal disease had vanished, and the child lived to die several months later of acute middle-ear disease. The necropsy showed extensive healing of tuberculosis in the peritoneal cavity and elsewhere. Among the reviews of original papers on tuberculosis in childhood there is one in which the value of a single Pirquet test is shown to be very untrustworthy. Of 800 children thus tested only 537 gave a positive reaction to the first Pirquet test with old tuberculin. Of the remaining 263 cases as many as 170, or 64·6 per cent., gave a positive tuberculin reaction either to a second Pirquet test or to the intracutaneous injection of old tuberculin in varying strengths.

FAITH AND PRACTICE.

IT is always rather difficult for a nonconformist of any complexion to understand the principles of the true faith, and when the *Homœopathic World* (No. 690, June, 1923) says that THE LANCET has " acknowledged the truth of the homœopathic principle." it is interesting to wonder to which or what principle assent has been given. Is it the original doctrine that *similia similibus curantur?* Or is it the more modern development which claims that drugs are effective in dilutions which would not contain a single molecule of the original active agent? Or is it the attribution of natures and qualities and emotions to plants which can be apprehended and used only by those in spiritual communion with the sources of drugs? It would be as difficult for the orthodox medical practitioner to draw up his creed of allopathy. Upon some of the clauses in both cases there would, we imagine, be insoluble differences of belief. But does this greatly matter when there is so much that is plain and fundamental from which no one will dissent? *In certis unitas, in dubiis libertas, in omnibus charitas.* No cult of medical men could have a better motto. And if it is followed in practice—and the more unconsciously the better—there is not much need to embark on the dangerous sea of putting down on paper what each group believes. They can all meet on the common ground of sincere humane and skilful work.

THE REGISTRATION OF DISEASE.

HOSPITAL statistics run largely to waste. This is, we think, the main lesson of a very interesting discussion on the Registration of Disease, opened by Dr. Reginald Dudfield at a meeting of the Royal Statistical Society last March,[1] and now reprinted. In his opening remarks at this discussion Dr. Dudfield pleaded for a utilisation of the records of sickness which accumulate in our general hospitals and other institutions for the treatment of disease. " It is a common experience," he said, " to read reports by different workers, dealing apparently with similar material, diametrically contradictory to each other." What is needed is the bringing together of the data derivable from all institutions, the collation and analysis of such data by a central body of statisticians who are not only statisticians but medical men of ripe judgment, well versed in the problems of public health. Other medical statisticians, Dr. T. H. C. Stevenson and Dr. Major Greenwood, and such eminent experts in public health matters as Sir William Hamer and Dr. John McVail, were in sympathy with Dr. Dudfield's general contentions. Dr. Stevenson pointed out that, even without drastic reform of the present system, some improvements might be effected. He instanced the emendation of the law required to secure knowledge of the sex and age distribution of cases of infectious disease, and suggested that a very good indication of the social class of each decedent would be afforded by a mere record of the number of rooms in the tenement occupied by the family. Dr. Greenwood dwelt upon the importance of a proper exploitation of hospital statistics, supplemented by a system of following up cases, in the study of the prognosis after operative or other treatment of malignant disease. Dr. Hamer advised Dr. Dudfield " in addition to trying to get more out of his Poor-law and health statistics " to try " to persuade the hospital authorities to introduce the study of disease as a mass phenomenon to their medical students." The medical profession as a whole will, we think, be in sympathy with Dr. Dudfield's ideas. Without doubt the economic and administrative difficulties of any centralisation of records are great, but the fact remains —and it is worth repeating and italicising—that, to a large extent, hospital experience *as a statistical datum* runs to waste. Of course, its value as such is only secondary, the highest use for hospital experience is its incorporation in the minds and practice of each generation of physicians and surgeons. But there is no opposition between these purposes. Sir William Osler could not be accused of having underrated the practical element in medical education, but, in his text-book, he employed the statistical method more fully and frequently than any other physician of his time. Dr. Dudfield's proposals would have had the full approval of that great physician.

A MILK-BORNE EPIDEMIC OF GASTRO-ENTERITIS.

A RECENT epidemic of milk-borne gastro-enteritis in Denmark has been the subject of instructive investigations by Dr. A. Christensen and Veterinary Surgeon P. Grinsted,[1] who claim that for the first time (with the possible exception of Dr. K. F. Meyer's case reported in the *Journal of Infectious Diseases* for 1916) proof positive has been found of a typical bovine paracoli infection being conveyed by cow's milk to man. The epidemic in question broke out on Oct. 11th, 1922, in a large hospital. Thirty-nine of the staff and 56 of the patients were seized with general malaise, fever, abdominal pain, nausea, headache, vomiting, and diarrhœa. In two cases there was an outbreak of herpes on the upper lip, and in one case there was partial loss of consciousness for 24 hours. None of the patients died, and no new cases occurred after the first outbreak. The incubation period was evidently very short, as was also the period during which the disease was contracted; for among the patients there was one who had been admitted to hospital for some other disease only the day before the outbreak occurred, and none of the persons admitted to hospital on the morning of the outbreak developed gastro-enteritis. All the patients had taken unboiled milk, and an inspection of the sources of the milk-supply led to the discovery that at a small farm one of the 13 cows in milk had fallen ill on Oct. 9th. Next day it had been very ill, with offensive diarrhœa and a temperature of 40° C. The cow died in the night of the 11th and 12th, but the milk yielded on the 9th had not been thrown away, although the cow's udder was œdematous. The necropsy on the cow showed definite signs of septicæmia, the spleen being gigantic and the liver and mucous lining of the small intestine showing acute inflammatory changes. Sections of the udder showed early mastitis which was evidently secondary to the enteritis and septicæmia. Numerous Gram-negative short bacilli, identified as bovine paracoli bacilli, were found in the spleen and secretion from the udder. A pure culture of the same bacilli was obtained from the fæces of two of the patients, and agglutination tests of the sera of 31 patients on the ninth to the twelfth day of the disease left little doubt as to the relation of the germs found in the cow to the epidemic in man. There is a disease in cattle, known in Denmark as " paracoli bacillosis," from which calves often suffer, but to which full-grown cattle are usually immune. It may be that this comparative immunity of full-grown cattle to paracoli bacilli explains the rarity with which human adjacent to or completely surrounding an ovum. In the older lesions the ovum was surrounded by dense fibrous tissue. Examination of the blood one month after the operation showed a leucocytic count of 5600; polymorphonuclears, 24 per cent.; small lymphocytes, 52 per cent.; large mononuclears, 7 per cent.; eosinophils, 17 per cent. No ova were found in the stools. Improvement took place under treatment by intravenous injections of sodium antimony tartrate in 2 per cent. solution, until in May, 1922, 14 months after the operation, the blood count showed that the eosinophils had fallen to 1·5 per cent. In the following August the patient was in excellent health and no evidence of bilharzia was found.

LABORATORY DIAGNOSIS OF VENEREAL DISEASE.

THE first edition of the Medical Research Council's report on the laboratory diagnosis of gonococcal infections and methods for the detection of *Spironema pallidum* is well known to all those engaged in the laboratory diagnosis of venereal disease, and the service which it has rendered in this field of work is undoubted. Unfortunately, it has been unobtainable latterly, having been out of print for some months. It will, therefore, be a matter of great satisfaction to those engaged in venereal diagnosis to know that a second edition[1] is now available. At the important discussion on Metastatic Gonorrhœa, the conclusion of which is reported on p. 18, doubt was thrown on the validity of some of the assumed localisations of gonorrhœal infection, in the absence of actual demonstration there of the virus. The first part of the report, dealing with the laboratory diagnosis of gonococcal infections, which has been revised and brought up to date by Dr. G. T. Western, is therefore of special value. Amongst the improvements to be noted here is the reduction in the number of alternative media given for the cultivation of the gonococcus. The preparation of nutrient agar—which can be enriched with human plasma or serum—and of tryptamine blood-extract agar and broth is dealt with in detail and gives a sufficient choice without being excessive. A valuable addition has been made to that portion of the report by Mr. J. E. Barnard which treats with the demonstration of spirochætes by dark-ground illumination. This is a method for differentiating between *S. pallidum* and other spironemata. Briefly, this method consists in estimating the number of spirals in the spirochæte to a given length, the standard suggested being the diameter of a red blood cell. As it is not a common occurrence to find spironemata in close proximity to red cells in the preparations, an ingenious eye-piece scale has been devised which introduces a number of artificial blood cells into the field of view. The procedure is simple and the apparatus inexpensive, and it should prove of very material aid in arriving at a correct diagnosis. Revising the section which treats of the staining methods to be used for spironemata, Dr. Clifford Dobell has added some valuable advice on the use of Romanowsky stains, which will be read with advantage by those making use of this procedure. The new edition of this report should prove of even greater value than its predecessor.

THE Canadian Parliament has unanimously voted to Dr. F. G. Banting an annuity of $7500 (£1500) to enable him to carry on his scientific work.

THE Gold Medal of the Royal Society of Medicine, "awarded triennially to a scientist, man or woman, who has made valuable contributions to the science and art of medicine," has this year been awarded to Prof. F. Gowland Hopkins, F.R.S., Professor of Biochemistry in the University of Cambridge.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXVII.—THE TREATMENT OF ASTHMA.

USED in its broadest sense, the term asthma is applied to a state of affairs in the smaller bronchi, which hinders the exchange of air between the larger bronchi and the alveoli of the lungs. We know little about the nature of the obstruction, but arguing from the analogy of the plain muscle of the intestine or bladder, we may assume that the bronchial muscle, which possibly contracts slightly during each normal expiration, may in asthma at one time be tonically contracted, and at another time undergoing a series of violent rhythmic contractions and relaxations. Œdema or congestion of the mucous membrane may also play a part, and is, perhaps, especially important in those cases where there is sensitisation to foreign proteins, inasmuch as the latter may produce œdema elsewhere—e.g., urticaria or angio-neurotic œdema.

From the definition given above we see that the term asthma is often used to denote a symptom, or perhaps a syndrome, rather than a disease—a syndrome in fact that may be caused by different agents. Thus in considering the treatment of asthma it is essential to diagnose the underlying cause.

(1) *Sensitisation to a Foreign Protein.*

In this case the asthma may be associated with other symptoms, such as coryza, gastro-intestinal disturbances, urticaria, angio-neurotic œdema, eczema, or acute dermatitis. Hay fever due to grass pollen is the commonest variety, but there are also the animal asthmas, where the hairs or feathers are responsible, and sensitiveness to certain foods or beverages, such as cereals, eggs, potatoes, lobster, strawberries, cocoa, &c. These foods usually produce gastro-intestinal disturbances in susceptible people, but asthma may occur as well. Finally, there may be a sensitiveness to micro-organisms of the respiratory or alimentary tracts, or to certain drugs. In some cases the diagnosis follows from the history of the case. But in any case, testing may be carried out with a series of proteins, which can be obtained commercially. The skin after cleaning is slightly scarified, and the solution of the protein applied by means of a platinum loop. If the protein is in powder form, it may be added to a drop of N/10 sodium hydrate, which has been placed over the scarified area. An urticarial wheal of at least ¼ inch in diameter indicates a positive result. Single protein testing, though it gives more satisfactory results, is a rather tedious business, and can be made shorter by the combination of various allied proteins—e.g., cat's, dog's, and horse's hair into a group, with various feathers, so that a single test answers for several different proteins. Some workers in this country and America have found that as many as 50 per cent. of asthmatics are sensitive to some foreign protein; but usually the positive results are much fewer than this. Sometimes patients rather disconcertingly react once and fail to react next time.

If a particular protein is answerable the best treatment is to avoid its presence altogether. Hay fever patients should stay in town in the early summer, or use a thick veil when walking in the country. Articles of diet containing the specific substance should not be eaten. If prevention is unsuccessful, desensitisation may be carried out by means of hypodermic injections of the specific protein in gradually increasing doses. Oral administration has also been carried out, particularly in France. These various antigens may be obtained commercially. Sensitiveness in hay fever may be tested by subcutaneous injections or by dropping solutions, gradually increasing in strength, of a mixture of pollen extracts into the eye, and after a few minutes examining for slight signs of inflammation. When a reaction is obtained, desensitisation may be carried out by injecting 1 c.cm. of a solution slightly weaker than that never yet been diagnosed before operation, but the writer suggests that in older cases a diagnosis might be established by X rays. The outcome of twin tubal pregnancies is recorded in 40 cases: 29 recovered, 10 died, and 1 was not recognised until the autopsy.

[1] Medical Research Council Special Report Series, No. 19 revised). H.M. Stationery Office. Price 1s. 6d.

ARE FEMALES LOSING THE ADVANTAGE OF LOW MORTALITY?

THE differences in vitality of the two sexes are of perennial interest to the physician as well as to the statistician, and no completely satisfactory explanation of these differences at various ages has been advanced. Both in the United States and in this country this difference is shown even in the first year after birth. Thus in the year 1920 in the registration area of the United States the female death-rate among infants under 1 year of age was 20 per cent. and in England and Wales was 23 per cent. lower than the male infant death-rate, and an excess of male over female rate of mortality was shown consistently in each month of infancy. After infancy in the United States the excess of male over female mortality continues throughout each stage of life; while in England and Wales at ages 10–15 there is seen some excess of female over male mortality. The ages at which this excess of female over male mortality occurs in England have gradually narrowed with the course of time; and the absence of this feature in America is interesting.

In the May issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company of New York attention is drawn to the fact that in the experience of persons insured in this company a reversal of the usual relationship occurred, the female mortality at all ages exceeding the male by 2·6 per cent. in 1920, while the male excess in 1922 was 1·2 per cent. Among white insured persons an excess of female mortality over male occurred at ages 15–35 in 1920. These oscillations in the relation of male to female mortality are interesting, but their explanation is obscure. The factors producing this result are not confined to insured persons, for in 1920 taking the whole of the American registration area the death-rate at ages 20–25 and at ages 25–35 was higher in women than in men. These differences of experience in the American statistics will deserve further study, directed to a determination of the causes of excess of female over male mortality in each age-period. It is probable that similar studies of various large towns in this country would reveal exceptional sex-incidence of mortality at different ages, and that thus much light might be thrown on possibilities of preventive work. A great difficulty in pursuing this line of investigation is constituted by the delay in the issue of the census reports for a large number of counties, as without a statement of the 1921 population according to age and sex detailed death-rates cannot be calculated.

CHRONIC ECZEMA PRODUCED BY WHEAT-FLOUR.

A CASE of sensitisation to wheat-flour which produced chronic eczema is well reported[1] by Dr. H. Grenet and Dr. R. Clement. A woman of 63 had developed the trouble at 40; the lesion was so extensive and itched so badly as to preclude sleep, and this in spite of constant attempts at treatment. Inquiries into the family history showed nothing—no eczema that is, for the authors do not say if other types of toxic idiopathy were looked for. Finding that among the various drastic food restrictions bread seemed to be the only foodstuff which had never been curtailed, they prescribed a normal dietary, minus bread; and bread proved indeed to be the disturbing factor, for the patient improved forthwith. It is worth noting that a very definite intradermal reaction was obtained with flour mixed with normal serum, but this mixture gave no skin reaction. At this stage 100 g. of bread were deliberately administered and produced the typical blood crisis—drop of pressure in five minutes and a leucopenia reaching a maximum after 45 minutes. Desensitisation was effected with the same wheat and serum mixture; details are given in culinary terms—"one coffee-spoon of flour to two dessert-spoons of serum"; doses of half and later of 1 c.cm. of this mixture proved effective in spite of a somewhat sharp general reaction. The patient was then habituated to a bread diet by easy stages, till after three months she was allowed normal diet. Even then she was afraid to eat green peas or strawberries—foods which had previously provoked attacks of eczema; but on trial she found that these no longer harmed her. This additional success the authors ascribe to a wide group-desensitisation; and, given any specificity at all, the group must indeed be wide which includes wheat, strawberries, and green peas! We would suggest rather that, on the summation theory of protein irritants, while bread had been a constant factor making for trouble any other irritant could always produce an increase of symptoms, but with the wheat factor removed by desensitisation other and slighter irritants were not enough to cause an attack. The authors quote another less clearly established instance of wheat-eczema, and note that Sabouraud has pointed out the dangers of bread in certain cases; they conclude that such cases are commoner than is generally supposed. This may be true; but it is also true that seldom can the protein cause for eczema and asthma be established as quickly and certainly as in the case of Dr. Grenet and Dr. Clement.

BILHARZIAL APPENDICITIS.

Dr. C. H. Bailey and Dr. E. A. Bullard,[1] of Woman's Hospital, New York, who describe a case which came under their own observation, remark that though infections with the trematode parasite schistosoma are very common in certain parts of the world, especially Africa, cases in which the symptoms are confined to the vermiform appendix are extremely rare. As is well known, the commonest sites of infection by the *Schistosoma hæmatobium* described by Bilharz in 1852 are the bladder and urethra, rectum, vulva, and vagina. Urinary symptoms, especially hæmaturia, are the commonest, both in the male and in the female, in whom bilharzia infections, according to Burfield, are 24 times less frequent than in the male. The writers have been able to find only two previous cases on record in which symptoms of bilharzia infection were confined to the appendix. The first was that described by J. Burfield in THE LANCET[2] in a man aged 36, in whom abundant ova of schistosoma were found in the submucosa of a suppurating appendix. The patient had no symptoms of genito-urinary or rectal involvement. The other case is one attributed to Aireton by Kelly of exclusive localisation of the ova of the parasite in the appendix, but no further description is given. The writers' case occurred in a woman, aged 25, who had lived in South Africa until she was 15. Her chief complaints were sterility, dysmenorrhœa, and frequent dull pains in the right lower quadrant of the abdomen for nearly two years. Examination showed an undeveloped uterus with stenosis of the cervix and evidence of chronic appendicitis which was confirmed by operation, when the entire meso-appendix and distal two-thirds of the appendix were found to be thickly studded with tiny greyish-white nodules resembling tubercles. Microscopical sections showed that the nodules were present in moderate number in the submucous and serous coats and throughout the meso-appendix. There were none in the mucous membrane or muscular layer. The nodules contained one or more ova with a very definite cell membrane, some of which were calcified. Numerous giant cells with many nuclei were seen adjacent to or completely surrounding an ovum. In the older lesions the ovum was surrounded by dense fibrous tissue. Examination of the blood one month after the operation showed a leucocytic count of 5600; polymorphonuclears, 24 per cent.; small lymphocytes, 52 per cent; large mononuclears, 7 per cent.; eosinophils, 17 per cent. No ova were found in the stools. Improvement took place under treatment by intravenous injections of sodium antimony tartrate in 2 per cent. solution, until in May, 1922, 14 months after the operation, the blood count showed that the eosinophils had fallen to 1·5 per cent. In the following August the patient was in excellent health and no evidence of bilharzia was found.

LABORATORY DIAGNOSIS OF VENEREAL DISEASE.

THE first edition of the Medical Research Council's report on the laboratory diagnosis of gonococcal infections and methods for the detection of *Spironema pallidum* is well known to all those engaged in the laboratory diagnosis of venereal disease, and the service which it has rendered in this field of work is undoubted. Unfortunately, it has been unobtainable latterly, having been out of print for some months. It will, therefore, be a matter of great satisfaction to those engaged in venereal diagnosis to know that a second edition[1] is now available. At the important discussion on Metastatic Gonorrhœa, the conclusion of which is reported on p. 18, doubt was thrown on the validity of some of the assumed localisations of gonorrhœal infection, in the absence of actual demonstration there of the virus. The first part of the report, dealing with the laboratory diagnosis of gonococcal infections, which has been revised and brought up to date by Dr. G. T. Western, is therefore of special value. Amongst the improvements to be noted here is the reduction in the number of alternative media given for the cultivation of the gonococcus. The preparation of nutrient agar—which can be enriched with human plasma or serum—and of tryptamine blood-extract agar and broth is dealt with in detail and gives a sufficient choice without being excessive. A valuable addition has been made to that portion of the report by Mr. J. E. Barnard which treats with the demonstration of spirochætes by dark-ground illumination. This is a method for differentiating between *S. pallidum* and other spironemata. Briefly, this method consists in estimating the number of spirals in the spirochæte to a given length, the standard suggested being the diameter of a red blood cell. As it is not a common occurrence to find spironemata in close proximity to red cells in the preparations, an ingenious eye-piece scale has been devised which introduces a number of artificial blood cells into the field of view. The procedure is simple and the apparatus inexpensive, and it should prove of very material aid in arriving at a correct diagnosis. Revising the section which treats of the staining methods to be used for spironemata, Dr. Clifford Dobell has added some valuable advice on the use of Romanowsky stains, which will be read with advantage by those making use of this procedure. The new edition of this report should prove of even greater value than its predecessor.

THE Canadian Parliament has unanimously voted to Dr. F. G. Banting an annuity of $7500 (£1500) to enable him to carry on his scientific work.

THE Gold Medal of the Royal Society of Medicine, "awarded triennially to a scientist, man or woman, who has made valuable contributions to the science and art of medicine," has this year been awarded to Prof. F. Gowland Hopkins, F.R.S., Professor of Biochemistry in the University of Cambridge.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXVII.—THE TREATMENT OF ASTHMA.

USED in its broadest sense, the term asthma is applied to a state of affairs in the smaller bronchi, which hinders the exchange of air between the larger bronchi and the alveoli of the lungs. We know little about the nature of the obstruction, but arguing from the analogy of the plain muscle of the intestine or bladder, we may assume that the bronchial muscle, which possibly contracts slightly during each normal expiration, may in asthma at one time be tonically contracted, and at another time undergoing a series of violent rhythmic contractions and relaxations. Œdema or congestion of the mucous membrane may also play a part, and is, perhaps, especially important in those cases where there is sensitisation to foreign proteins, inasmuch as the latter may produce œdema elsewhere—e.g., urticaria or angio-neurotic œdema.

From the definition given above we see that the term asthma is often used to denote a symptom, or perhaps a syndrome, rather than a disease—a syndrome in fact that may be caused by different agents. Thus in considering the treatment of asthma it is essential to diagnose the underlying cause.

(1) *Sensitisation to a Foreign Protein.*

In this case the asthma may be associated with other symptoms, such as coryza, gastro-intestinal disturbances, urticaria, angio-neurotic œdema, eczema, or acute dermatitis. Hay fever due to grass pollen is the commonest variety, but there are also the animal asthmas, where the hairs or feathers are responsible, and sensitiveness to certain foods or beverages, such as cereals, eggs, potatoes, lobster, strawberries, cocoa, &c. These foods usually produce gastro-intestinal disturbances in susceptible people, but asthma may occur as well. Finally, there may be a sensitiveness to micro-organisms of the respiratory or alimentary tracts, or to certain drugs. In some cases the diagnosis follows from the history of the case. But in any case, testing may be carried out with a series of proteins, which can be obtained commercially. The skin after cleaning is slightly scarified, and the solution of the protein applied by means of a platinum loop. If the protein is in powder form, it may be added to a drop of N/10 sodium hydrate, which has been placed over the scarified area. An urticarial wheal of at least ¼ inch in diameter indicates a positive result. Single protein testing, though it gives more satisfactory results, is a rather tedious business, and can be made shorter by the combination of various allied proteins—e.g., cat's, dog's, and horse's hair into a group, with various feathers, so that a single test answers for several different proteins. Some workers in this country and America have found that as many as 50 per cent. of asthmatics are sensitive to some foreign protein; but usually the positive results are much fewer than this. Sometimes patients rather disconcertingly react once and fail to react next time.

If a particular protein is answerable the best treatment is to avoid its presence altogether. Hay fever patients should stay in town in the early summer, or use a thick veil when walking in the country. Articles of diet containing the specific substance should not be eaten. If prevention is unsuccessful, desensitisation may be carried out by means of hypodermic injections of the specific protein in gradually increasing doses. Oral administration has also been carried out, particularly in France. These various antigens may be obtained commercially. Sensitiveness in hay fever may be tested by subcutaneous injections or by dropping solutions, gradually increasing in strength, of a mixture of pollen extracts into the eye, and after a few minutes examining for slight signs of inflammation. When a reaction is obtained, desensitisation may be carried out by injecting 1 c.cm. of a solution slightly weaker than that which caused the ophthalmic reaction, and repeating this every three or four days. The ophthalmic reaction may be re-determined at intervals, and the amount of the injections regulated accordingly. Hydrated calcium chloride in doses of 15 gr. dissolved in water three times a day may be of value in the prevention of hay fever.

(2) *Idiopathic Asthma.*

In the same way that certain people seem to be affected with an irritable stomach, so we must imagine that a peculiarly sensitive neuro-muscular mechanism in the smaller bronchi is responsible for this group of asthma cases. In such people reflex disturbances in other parts of the body, hidden infection, and emotions may cause attacks. The attack may come on merely because the patient expects it; much good may be done by encouraging him to fight against this kind of suggestion. Worry, excessive physical or mental strain—e.g., sitting for examinations or overwork—must be avoided. If possible, a climate and surroundings should be chosen that suit the patient. The bowels must be made to act regularly; daily exercise should be taken in the fresh air; holidays should be regular. Indigestible food must be avoided, particularly at night.

Sources of infection must be eradicated, especially carious teeth showing apical infection. Dental X ray films may be of great value in diagnosis. The tonsils must be examined for disease and removed if heavily infected. Autogenous vaccines may be used. Care must be taken that children are not mouth-breathers, and, if so, simple respiratory exercises, such as deep inspirations through the nose, should be practised three or four times a day. It may be necessary to remove adenoids. In previous years various operations on the nose have had considerable vogue in the treatment of asthma, but they are now less popular.

Of recent years non-specific protein therapy has been used for asthma. The successful results obtained with stock vaccines made up from catarrhal organisms or mixed strains of *B. coli* are probably not due to their specificity against particular organisms present in the naso-pharynx or bronchi of the individual; they act because they contain foreign proteins. Peptone injections are often used for the same reason. Auld[1] advises a 5 per cent. solution of Armour's No. 2 peptone injected intramuscularly or intravenously. The first dose is 0·3 c.cm., and is gradually increased by 0·2 c.cm., the maximum dose being 2 or 2·5 c.cm. Injections are given twice weekly. The maximum dose advisable is one that just fails to give a reaction, and the temperature should be taken four or five hours after the injection, to see whether it is raised. Peptone is also given orally. Liquor arsenicalis in 5-minim doses, bromides, and particularly potassium iodide in doses up to 30 gr. a day are the most valuable drugs to prevent the onset of attacks. Mild purgation with calomel in small doses is also of value, and salol and other intestinal disinfectants have been used.

(3) *Asthma due to Infection of the Respiratory Tract.*

Asthma is often secondary to acute or chronic catarrhal infection of the upper respiratory tract, so that if the latter can be prevented or arrested, the attacks of asthma will cease. The treatment devised by Mr. Wilfrid Glegg of Birmingham is of the greatest value for naso-pharyngeal infection, and should always be tried before more elaborate means are adopted. The following is a simple way of carrying it out. A nasal funnel (these are made for me by Down Bros.) is filled with a mixture of 1 part white vaseline and 3 or 4 parts of liquid paraffin. This is allowed to run down each nostril in turn with the patient in a recumbent position, until it is felt in the naso-pharynx, when it may be swallowed. This process is carried out night and morning in chronic infection, but should be repeated 4-hourly to prevent the onset of an acute coryza, as soon as the first symptoms are noticed. It is not always possible to prevent altogether the onset of some tracheitis and bronchitis, but in my experience they are less severe than if the naso-pharyngeal infection had run its usual course.

Autogenous vaccines may be prepared from the sputum, or from swabs passed through the anterior nares into the naso-pharynx or from the naso-pharynx directly. Immediate planting out and incubation of the material is advisable. Stock vaccines may be employed, and these bacterial infections may yield to non-specific protein therapy as already described. In the chronic bronchitis and asthma so common in elderly people, many of the drugs detailed below may be used, but in addition expectorants will be useful for the bronchitis, and it may be necessary to treat incipient cardiac failure. Asthma may be present with phthisis, and treatment of the phthisis may relieve the asthma.

(4) *Treatment of an Asthmatic Attack.*

A large number of drugs have been successful in cutting short an attack of asthma or in relieving the difficulty of breathing that persists after the climax of the attack is over. A subcutaneous injection of 1 or 2 ♏ of adrenin (1 in 1000) may answer, though 10 or even 15 ♏ have been injected intramuscularly. Recently, benzyl benzoate has been administered in 20-drop doses 4-hourly, by the mouth or subcutaneously. Maximal pharmacopœial doses of tr. lobeliæ æth., tr. stramonii, tr. belladonnæ, choral hydrate, the nitrites, or nitro-glycerine may be given by mouth. Inhalation of amyl nitrite, chloroform, or the fumes made by igniting the B.P.C. mixture of potassium nitrate, lobelia, stramonium leaves, and anise fruit in equal parts, are often used during the acute attack, and cigarettes containing stramonium are smoked; but a warning must be sounded in regard to the frequent inhalation of fumes, as they irritate the bronchi, causing inflammation, and this predisposes to future attacks. Injections of atropine gr. 1/100 to 1/50 may be of value, but morphia, although very effective, must not be used if the attacks are frequently repeated, and the same applies to sprays containing cocaine.

Great relief will be experienced with oxygen inhalation, which, to be effective, must be given by means of a mask, such as that supplied with Haldane's apparatus (an anæsthetic mask will answer satisfactorily) or by means of a nasal catheter pushed right back into the naso-pharynx. The secret of successful oxygen treatment is to give it in sufficient quantity. It may be bubbled through water, so quickly that the bubbles cannot be counted. The flow must be at least 2 litres a minute to begin with, and if there is no gauge on the cylinder, it is a simple matter to test the rate by delivering the oxygen through a rubber tube beneath a pint measure which has been filled with water and inverted in a basin of water. The flow should be quick enough to displace the water in from 15 to 20 seconds. Attacks may also be stopped by hot baths, particularly if the patient inspires cool air from an inhaler which has been packed with ice.

(5) *Breathless Attacks in Elderly Subjects.*

Many elderly people are prone to attacks of breathlessness, particularly at night-time. The heart not uncommonly shows some evidence of failure, and the patients also notice that they soon get out of breath with exercise. There is emphysema and the breathing at times may become periodic, somewhat resembling Cheyne-Stokes respiration. Such cases have been called cardiac asthma. There may be some albuminuria, but although the urea in the blood is perhaps a little raised, there is no increase of fixed acid, and so these cases are not uræmic. Their pathology is rather obscure, but some recent evidence[2] points to the breathless attacks being due to bronchial spasm. Antispasmodic remedies may be of some value, but oxygen is the chief stand-by. Here again it is important to use a comparatively rapid flow, and administer it through a mask and valves, or nasal catheter. The wasteful and ineffective glass funnel should not be used.

E. P. POULTON, M.D. Oxf., F.R.C.P. Lond.,
Physician to Guy's Hospital.

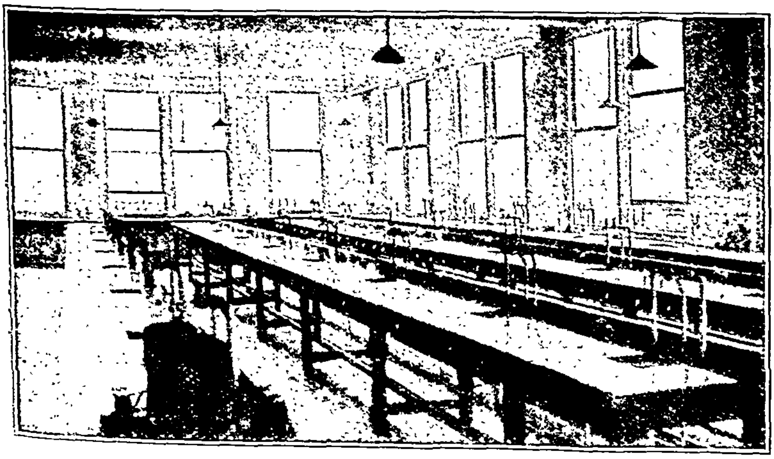
Special Articles.

GUY'S HOSPITAL MEDICAL COLLEGE.

NEW ANATOMY, BIOLOGY, AND PHYSICS DEPARTMENTS.

BEFORE a distinguished company the formal opening of the new Anatomy, Biology, and Physics Departments by the Prince of Wales, President of the hospital, took place on July 2nd. The Prince, who was received by the Treasurer of the Hospital, Lord Goschen, and Mr. H. J. Waring, Vice-Chancellor of the University of London, proceeded to a platform erected outside the Medical School, where an address was read by the Dean of the Medical School, Dr. T. B. Johnston. In the address the scheme of rebuilding the Medical School, begun in 1897 with the physiology department and now completed by the opening of this new extension, was outlined, as well as the means by which financial difficulties were overcome, at least temporarily. The total cost of the buildings was £100,000, and part of this had to be found by borrowing; it was hoped that other benefactors would come forward to relieve the school of the incubus of debt and so enable it to carry on the work in a manner worthy of the great traditions of Astley Cooper, Bright, Addison, Gull, and Wilks. The Prince of Wales, in opening the new extension, referred to the great value of medical research and to the national importance of the work of the great voluntary hospitals and their medical schools. Science and industry alone were not enough; the sinews of war on disease must also be forthcoming, and the door of the treasurer's department was open as continuously as that of the hospital. A vote of thanks to His Royal Highness, proposed by Dr. J. Fawcett, senior physician, and seconded by Sir Alfred Fripp, senior surgeon to the hospital, was carried with acclamation, after which the Prince inspected the new buildings. After the ceremony the guests and friends of the hospital had an opportunity of inspecting the Medical School buildings as well as the wards of the hospital.

FIG. 2.



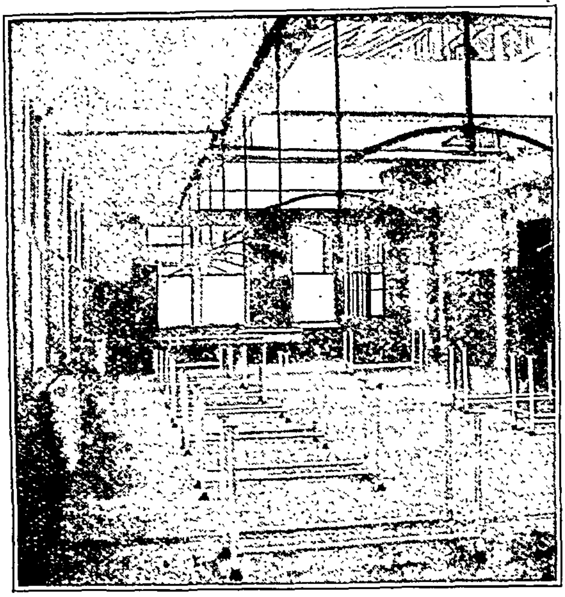
The new department of histology.

Refreshments were served in marquees in the grounds and the band of H.M. Coldstream Guards played appropriate music.

The New Buildings.

The extension provides new anatomical, biological, and physics departments, together with additional accommodation for physiology and surgery. Every possible means has been taken to render the interior of the building as light as possible, the external walls having large windows on three sides and the interior walls being of white glazed brick below and having glass partitions above as far as practicable. In the dissecting room, the operative surgery room, and the surgical research room, terrazo flooring replaces the wood blocks used in the rest of the building. The building comprises three floors and a basement; the roof has been made flat with a view to providing space for animal hutches and water tanks for breeding fresh water animals. The third floor is entirely devoted to human anatomy and contains a dissecting room, 80 feet by 24 feet, magnificently lit by large windows on three sides and by a large roof light, and having novel and elaborate arrangements for artificial lighting over each of the 16 tables (Fig. 1). A small demonstration theatre, capable of seating 50 students, leads off the dissecting room. There are also two specimen rooms and assistants' rooms. On the second floor is the histology laboratory, with well-arranged bench room for 73 students; communicating with the laboratory is a preparation room, where section cutting will be done for the anatomy, biology, and morbid histology departments, and for the Gordon Museum. Two small laboratories on this floor are intended for the private use of the lecturer on anatomy and the demonstrators, and there is also a large specimen room where reconstruction models of human and mammalian anatomy and embryology will be housed. The first floor is divided between the biology department, the physics department, and an operative surgery room, with a small surgical research room to be equipped as an operating theatre for experimental work on animals. The students' biology laboratory resembles the histology laboratory on the floor above, with slight modifications in the bench equipment and lighting. The physics department consists of a laboratory providing bench room for 50 students, an optical room, which will be shared by the physiology department, and research rooms for the lecturer and his demonstrators. The physics laboratory is equipped

FIG. 1.



The new dissecting room.

with teak-topped tables in which are covered sunken wells with a sink and water, electric and gas connexions. Power connexions are disposed where necessary. In the basement there are a number of rooms devoted to the anatomy department as well as a demonstration theatre capable of seating 70 students. There is a well-ventilated tank-room, connected with the other floors by an electric lift, a reception and preparation room, a store room, and a large workroom equipped with a machine for cutting frozen anatomical sections, as well as photomicrographic and dark rooms.

The new extension here described was designed largely with the object of providing better facilities for collaboration between the various non-clinical departments which are now, with the exception only of pathology and pharmacology, all housed under one roof. A rather striking rearrangement is the grouping of histology with human anatomy, but this is in line with the view that the study of microscopic and macroscopic anatomy should be closely associated. The provision of a room for surgical research in close association with the anatomy department was also well planned, and should be fruitful in work useful to the school and hospital. It is unfortunate, but inevitable, in such a district as the Borough that the new extension should be partly overshadowed by neighbouring buildings, so that, in spite of the very large window space, the lighting on the lower floors is not very good. This is particularly noticeable in the physics laboratory, where artificial lighting has had to be provided on a lavish scale, and applies also, though in lesser degree, to the histology laboratory. The lighting of the dissecting room, however, is magnificent, and this is perhaps the only department in which it is essential.

The buildings as a whole are admirably equipped, and students of Guy's cannot fail to react to the stimulating effect of spacious rooms so well adapted to their purpose. We congratulate them on their new college.

RESEARCH IN TROPICAL DISEASE.

III. The Lister Institute of Preventive Medicine.

Throughout its history the Lister Institute has never ceased to take an active share in elucidating problems of vital importance in tropical disease. It has been enabled to do so, not so much by the despatch of scientific experts to tropical regions, though this form of activity has by no means been ignored when the necessary funds permitted, as by providing facilities for systematic research, both static and experimental, in those basal sciences protozoology, entomology, bacteriology, experimental pathology, and biochemistry, &c., which determine more and more, as time goes on, the lines of solid advance.

In 1906 the late Prof. Minchin was granted laboratory accommodation in the Institute for his work as university professor of protozoology. A special department of protozoology was thus formed in which systematic research on protozoa generally, as well as on those responsible for disease in man and animals, could be intensively followed. Even before the arrival of Minchin some notable studies on the experimental infection of rats with trypanosomes and the influence of chemotherapeutic agents on such infections, by the late Prof. Plimmer and various collaborators, had emanated from the Institute. From Prof. Minchin's department came many important contributions to our knowledge of trypanosomes and, more especially, of their developmental cycles in hosts like the tsetse-fly and the rat flea. Both Prof. Minchin and Miss Muriel Robertson also enjoyed a lengthy field experience in Uganda in connexion with their trypanosome studies. The Indian Plague Commission, appointed jointly by the Secretary of State for India, the Royal Society, and the Lister Institute, engaged the services of various Institute experts, all of whom contributed materially, whether at home or at Bombay, to the solution of the plague problem as one determined essentially by the bionomics of the rat flea. To other plague-stricken areas, Manchuria, Egypt, &c., the Institute has lent its experts. In 1911 a department of entomology was instituted, in charge of which was placed the late Arthur Bacot, whose unique talents, already displayed in working out the bionomics of the rat flea on behalf of the Plague Commission, were thus recognised. Bacot's achievements during the following 12 years up to his lamented death from typhus in 1922 are possibly fresh in the minds of many readers, but here may be mentioned his work with C. J. Martin on the precise mechanism by which *B. pestis* is transferred from flea to rat, his elaborate study of the bionomics of *Stegomyia fasciata* for the West African Yellow Fever Commission, and his last experimental studies on the viruses of trench fever and typhus fever carried out at home, in Poland, and in Egypt.

The departments of protozoology and entomology, now sadly deprived of their distinguished chiefs, have throughout acted as nursing grounds for research workers from many lands in search of the knowledge that would render them more efficient for prosecuting research in tropical climes. No department of the Institute, however, has failed to yield its contribution to the sum total of studies specially devoted to tropical disease problems. Subjects such as snake-venom, bacillary dysentery, cholera, leprosy of man and rat, ankylostomiasis, and leishmaniasis have at various times engaged the attention of staff or voluntary workers, British and foreign. The departments of experimental pathology and biochemistry have, as is well known, undertaken, in recent years, intensive studies on certain diseases of nutrition, beri-beri, pellagra, rickets, osteomalacia, and scurvy. The boundary line between diseases of tropical and temperate climes wears somewhat thin at times, and such studies as these cannot fail to influence profoundly standards of hygiene and well-being in the tropics as elsewhere.

TREATMENT OF EARLY MENTAL CASES IN GENERAL HOSPITALS.

INAUGURATION OF WARDS AT MIDDLESEX HOSPITAL.

The two new wards at the Middlesex Hospital for the treatment of early mental cases "by members of the staff of St. Luke's Hospital" were formally inaugurated on June 28th, at a meeting attended by representatives of the public bodies concerned. It will be remembered that St. Luke's Hospital for Lunatics, formerly situated in Old-street, E.C., was closed in December, 1916, when it was announced that it was to be re-established as soon as circumstances would permit near Gerrards Cross, Bucks. At the present moment the hospital has central offices at 19, Nottingham-place, London, W. 1, and runs a convalescent home at Gerrards Cross, so that the establishment of beds in the Middlesex Hospital marks a considerable advance towards its actual re-establishment as a mental hospital.

Coöperation between St. Luke's and Middlesex Hospitals.

Lord Athlone, treasurer of the Middlesex Hospital, expressed his gratitude to the authorities of St. Luke's Hospital for the part they had played in bringing about the establishment of these wards. The principle of coöperation between general and special hospitals had been widely discussed and generally accepted, but he believed this to be the first example of carrying it into practice. Mr. Arthur Cross Powell, treasurer of St. Luke's Hospital, mentioned the fact that St. Luke's was founded in 1751, only six years later than the Middlesex, and had spent the greater part of its existence on a site which, although ample in size and held on a perpetual lease at an exceedingly low rental, had come to be surrounded by tram-routes, the noise of which by day and by night hardly contributed to the well-being of the patients. A few years ago the new site had been acquired in Buckinghamshire, and it was hoped to proceed with building there at an early date. He welcomed coöperation with the Middlesex Hospital in the present venture, and wished and predicted every success to it. Sir Coles Child described the new wards as a step beyond the out-patient departments which have already been established at some mental hospitals for the benefit of the same type of patient. The utility of these departments was seriously discounted by the fact that many people objected to going anywhere near an asylum. The present arrangement obviated this, while providing treatment by the staff of an institution devoted to the care of the insane. He saw no reason why general and mental hospitals should not coöperate in this way throughout the country. Dr. C. Hubert Bond, Commissioner of the Board of Control, expressed his great personal satisfaction, and that of the Board of Control, at the step which had been taken. Hitherto, the general hospital out-patient department had presented an impervious screen which no case of mental disease had been allowed to pass. He had long hoped that the Middlesex would find the means of doing something for these patients, and had advocated a scheme of this nature some years ago. The doors were now open, and he hoped that all teaching hospitals would follow suit.

The New Wards.

The new wards occupy the second floor of the out-patient department, which has been reconstructed for the purpose, and consist of a male and a female ward, each containing three beds, and lavatories, bathrooms, and nurses' room. The wards present a most attractive and restful appearance, being well-lighted, quiet, cool, and tastefully decorated in the manner of a bedroom in a comfortable private house. These wards are intended for the treatment of such cases of functional nervous disorder as appear likely to derive benefit by hospital in-patient treatment. Chronic cases, and those which have failed to respond to treatment elsewhere, as well as patients likely to cause annoyance to others, or cases of frank insanity, will not be admitted. Patients will be admitted from the out-patient department of the Middlesex Hospital, and during treatment they will be under the supervision of Dr. R. W. Gilmour, who was assistant medical officer of St. Luke's in its last years in the City. The resources of all the special departments in the hospital will be available for such methods of investigation and treatment as are found desirable.

NATIONAL BABY WEEK CONFERENCE.

THE Conference opened on Monday, July 2nd, and owing to the large number of delegates was held in the Caxton Hall instead of at Carnegie House, as originally intended.

Dr. G. F. STILL took the chair at the morning session, when the presidential address was delivered by the Rt. Hon. NEVILLE CHAMBERLAIN, M.P., Minister of Health. He said that, in his opinion, the most urgent matters calling for attention in regard to maternity and child welfare were an increase in the number of infant welfare centres and of health visitors, and schemes of this kind would be regarded by him with a favourable eye. He would like to see further provision to assist in reducing maternal and early infantile mortality, in which but little progress had been made, and an improved midwifery service. A great debt was owed to volunteers who started maternity and child welfare work, and there was no sphere in which voluntary assistance could be more profitably employed.

Dr. J. S. FAIRBAIRN opened the discussion on the

Causal Factors of Infant Mortality up to One Month of Age,

dealing specially with the antenatal causes. Maternal disease and prematurity, he said, were conditions largely affecting early infantile mortality, and the diseases likely to damage the child were those in which there was some poison of the system, chemical or bacterial, or where there was formation of deleterious products in the body or accumulation owing to defective elimination. Diseases due to poisons formed within the body included the group known as toxæmias of pregnancy, of which eclampsia was the most dramatic example; those due to defective elimination covered albuminuria, kidney disease, and the like, any of which might terminate the pregnancy or cause early death of the infant. It was common knowledge among obstetricians that mothers seriously ill often had average infants; the placenta and placental cells had first claim, and the fœtus lived like a parasite on the mother. Syphilis—a common cause of stillbirth and infantile death—was a curable disease, but hard to recognise in women at an early stage. Toxæmias of pregnancy, on the other hand, were usually easy to diagnose but hard to treat.

Dr. EARDLEY HOLLAND considered that intranatal causes of death might be summed up in the one word "injuries," the majority being injuries to the head. The delicate structure of the head at birth was liable to injury from forceps or even in spontaneous birth where there was a contracted pelvis. Tearing of the dura mater and cerebral hæmorrhage were specially apt to occur in premature cases, and intracranial injuries were frequent in breech presentations, the injury being caused by too quick rather than too slow delivery of the after-coming head. Dr. Holland had, in his experience, seen one infant of seven months, who died of something else, in whom a healed tear was visible.

Prof. LOUISE MCILROY said that birth should be considered as an episode, the nine previous months being regarded as equally important with later life. She believed sepsis was usually introduced by lacerations, however small they might be. In the period of rather more than two years that her special department had been working at the Royal Free Hospital there had been no case of eclampsia. The babies were not subjected to violent artificial respiration with exposure to cold air, but were wrapped in a warm towel, their respiratory passages cleared of mucus, and left quiet. They were oiled, but not washed for three days, to prevent shock and loss of heat.

The afternoon discussion on the

Value of Maternity Homes in a Maternity and Child Welfare Scheme.

was interesting for the variety of opinions expressed. Dr. JANET CAMPBELL, as chairman, said that the Ministry of Health's policy of a large number of small maternity homes had been criticised on the scores of extravagance in expenditure and staff, the difficulty of maintaining a high standard of midwifery practice in isolated units, and the small value of such institutions as training schools, all of which criticisms she thought were justified. In 1922 there were 107 maternity homes with 1275 beds; some had not been used to their full capacity, and Dr. Campbell thought that fees had perhaps proved deterrent though they were not meant to be so. There was some discussion as to the class of patient who should be eligible for maternity homes, most speakers favouring the view that they should be for normal cases. Differing views were held as to the advisability of utilising isolation hospitals for maternity cases, Dr. W. ALLEN DALEY and Dr. S. G. MOORE both approving the idea, Miss J. C. WISHART thinking it unwise, and Dr. E. R. WOODHOUSE, of Llandudno, feeling convinced that patients would be frightened to use them. A refreshing speech was made by Councillor Mrs. LEWIS, of Barry, who said she spoke as a working woman, and knew that the women of Barry regarded the home made for them by their own man as the only proper place in which to have their babies. She would greatly like to see a rota of efficient home helps who would take complete charge of the work of the homes for at least a fortnight.

with teak-topped tables in which are covered sunken wells with a sink and water, electric and gas connexions. Power connexions are disposed where necessary. In the basement there are a number of rooms devoted to the anatomy department as well as a demonstration theatre capable of seating 70 students. There is a well-ventilated tank-room, connected with the other floors by an electric lift, a reception and preparation room, a store room, and a large workroom equipped with a machine for cutting frozen anatomical sections, as well as photomicrographic and dark rooms.

The new extension here described was designed largely with the object of providing better facilities for collaboration between the various non-clinical departments which are now, with the exception only of pathology and pharmacology, all housed under one roof. A rather striking rearrangement is the grouping of histology with human anatomy, but this is in line with the view that the study of microscopic and macroscopic anatomy should be closely associated. The provision of a room for surgical research in close association with the anatomy department was also well planned, and should be fruitful in work useful to the school and hospital. It is unfortunate, but inevitable, in such a district as the Borough that the new extension should be partly overshadowed by neighbouring buildings, so that, in spite of the very large window space, the lighting on the lower floors is not very good. This is particularly noticeable in the physics laboratory, where artificial lighting has had to be provided on a lavish scale, and applies also, though in lesser degree, to the histology laboratory. The lighting of the dissecting room, however, is magnificent, and this is perhaps the only department in which it is essential.

The buildings as a whole are admirably equipped, and students of Guy's cannot fail to react to the stimulating effect of spacious rooms so well adapted to their purpose. We congratulate them on their new college.

RESEARCH IN TROPICAL DISEASE.

III. THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.

THROUGHOUT its history the Lister Institute has never ceased to take an active share in elucidating problems of vital importance in tropical disease. It has been enabled to do so, not so much by the despatch of scientific experts to tropical regions, though this form of activity has by no means been ignored when the necessary funds permitted, as by providing facilities for systematic research, both static and experimental, in those basal sciences protozoology, entomology, bacteriology, experimental pathology, and biochemistry, &c., which determine more and more, as time goes on, the lines of solid advance.

In 1906 the late Prof. Minchin was granted laboratory accommodation in the Institute for his work as university professor of protozoology. A special department of protozoology was thus formed in which systematic research on protozoa generally, as well as on those responsible for disease in man and animals, could be intensively followed. Even before the arrival of Minchin some notable studies on the experimental infection of rats with trypanosomes and the influence of chemotherapeutic agents on such infections, by the late Prof. Plimmer and various collaborators, had emanated from the Institute. From Prof. Minchin's department came many important contributions to our knowledge of trypanosomes and, more especially, of their developmental cycles in hosts like the tsetse-fly and the rat flea. Both Prof. Minchin and Miss Muriel Robertson also enjoyed a lengthy field experience in Uganda in connexion with their trypanosome studies. The Indian Plague Commission, appointed jointly by the Secretary of State for India, the Royal Society, and the Lister Institute, engaged the services of various Institute experts, all of whom contributed materially, whether at home or at Bombay, to the solution of the plague problem as one determined essentially by the bionomics of the rat flea. To other plague-stricken areas, Manchuria, Egypt, &c., the Institute has lent its experts. In 1911 a department of entomology was instituted, in charge of which was placed the late Arthur Bacot, whose unique talents, already displayed in working out the bionomics of the rat flea on behalf of the Plague Commission, were thus recognised. Bacot's achievements during the following 12 years up to his lamented death from typhus in 1922 are possibly fresh in the minds of many readers, but here may be mentioned his work with C. J. Martin on the precise mechanism by which *B. pestis* is transferred from flea to rat, his elaborate study of the bionomics of *Stegomyia fasciata* for the West African Yellow Fever Commission, and his last experimental studies on the viruses of trench fever and typhus fever carried out at home, in Poland, and in Egypt.

The departments of protozoology and entomology, now sadly deprived of their distinguished chiefs, have throughout acted as nursing grounds for research workers from many lands in search of the knowledge that would render them more efficient for prosecuting research in tropical climes. No department of the Institute, however, has failed to yield its contribution to the sum total of studies specially devoted to tropical disease problems. Subjects such as snake-venom, bacillary dysentery, cholera, leprosy of man and rat, ankylostomiasis, and leishmaniasis have at various times engaged the attention of staff or voluntary workers, British and foreign. The departments of experimental pathology and biochemistry have, as is well known, undertaken, in recent years, intensive studies on certain diseases of nutrition, beri-beri, pellagra, rickets, osteomalacia, and scurvy. The boundary line between diseases of tropical and temperate climes wears somewhat thin at times, and such studies as these cannot fail to influence profoundly standards of hygiene and well-being in the tropics as elsewhere.

TREATMENT OF EARLY MENTAL CASES IN GENERAL HOSPITALS.

INAUGURATION OF WARDS AT MIDDLESEX HOSPITAL.

THE two new wards at the Middlesex Hospital for the treatment of early mental cases "by members of the staff of St. Luke's Hospital" were formally inaugurated on June 28th, at a meeting attended by representatives of the public bodies concerned. It will be remembered that St. Luke's Hospital for Lunatics, formerly situated in Old-street, E.C., was closed in December, 1916, when it was announced that it was to be re-established as soon as circumstances would permit near Gerrards Cross, Bucks. At the present moment the hospital has central offices at 19, Nottingham-place, London, W. 1, and runs a convalescent home at Gerrards Cross, so that the establishment of beds in the Middlesex Hospital marks a considerable advance towards its actual re-establishment as a mental hospital.

Coöperation between St. Luke's and Middlesex Hospitals.

Lord Athlone, treasurer of the Middlesex Hospital, expressed his gratitude to the authorities of St. Luke's Hospital for the part they had played in bringing about the establishment of these wards. The principle of coöperation between general and special hospitals had been widely discussed and generally accepted, but he believed this to be the first example of carrying it into practice. Mr. Arthur Cross Powell, treasurer of St. Luke's Hospital, mentioned the fact that St. Luke's was founded in 1751, only six years later than the Middlesex, and had spent the greater part of its existence on a site which, although ample in size and held on a perpetual lease at an exceedingly low rental, had come to be surrounded by tram-routes, the noise of which a staff of one superintendent and four lecturers. The strength of the schools has continued to increase. During the years 1917 to 1922 the strength of the Rayapuram school increased from 310 to 569 and that of the Tanjore school from 148 to 276. The total strength of schools in 1921 was 1262 as against 662 in 1917. Accommodation and equipment are generally unsatisfactory; the provision of hostels has become an urgent necessity for all the schools.

(4) *Physical Education and Hygiene.*—The last quinquennial report stated that "the weak point about physical education is that those who stand most in need of physical culture get least of it." This state of affairs is passing away; all inspectors report on the advance made during the last five years. Scout troops have only been really organised in Madras since 1917, but by 1920 there were 280 scout troops and packs with a total of 500 officers and over 6000 scouts. In 1921 Government approved a new syllabus on hygiene for Forms I. to III.; this syllabus was translated into the principal vernaculars, and was adopted in all middle and secondary schools.

Beri-beri in Madras Presidency.

In 1918–20 Colonel R. McCarrison, I.M.S., at the instance of the Indian Research Fund Association, undertook an investigation into beri-beri. As a result of his inquiries it was found that in Madras Presidency the disease is confined to a narrow tract on the east coast comprising the districts of Ganjam, Vizagapatam, Godaveri, Kistna, Guntur, and Nellore. No cases of beri-beri have been reported from districts lying outside this strip of coast except for a few in Vellore and in Bellary Jail. The disease attains its maximum degree of endemicity in the Kistna district, lying between the Kistna and Godaveri rivers, and is particularly prevalent in the neighbourhood of the left bank of the Kistna. At the Fourth Congress of the Far Eastern Association of Tropical Medicine held in 1921 it was recommended that governments concerned should take action to discourage the case of milled rice which contains less than the standard minimum of four-tenths of 1 per cent. of P_2O_5. The Congress also recommended the appointment of a commission, to which each country would be asked to send a delegate, which would make recommendations as to the best methods of bringing beri-beri under control. Colonel McCarrison considered that the provinces of Madras, Burma, and Bengal were sufficiently affected to require legislation; in anticipation of such action a brief memorandum on the subject of the causes of beri-beri has been prepared by him in consultation with the Director of Public Health, and this has recently been issued by the Government of Madras for propaganda purposes, translations having been made into the local vernaculars of the districts affected. Legislation for milled rice may be impracticable under present conditions, and it seems more reasonable to diffuse knowledge of the disease and its prevention than to interfere with mill-owners and their machinery.

Chemical Examiner's Report for 1922.

Major C. Newcomb's report as usual contains a number of interesting details. The total number of cases and articles examined was 3824 against 3952 in 1921. Human poisoning cases numbered 220, and stain cases 399. He says:—

"The regularity throughout the year with which the murder cases are sent to us is striking. One would expect, I think, some seasonal variation in their numbers or some indication of the 'waves of crime' of which one reads from time to time in the newspapers. . . . So far as the statistics of this department show, there is no murder season in the Madras Presidency, and waves of crime if they exist must be very choppy ones."

Of the 220 cases of suspected human poisoning, 108 showed poison, giving a positive percentage of 49·1 as compared with 40·6 in 1921. The chemical examiner, however, regrets in this connexion that more time is not available for experimental use of new toxicological methods. Of the 108 human cases in which poison was detected, mercury was found in 32 cases, arsenic in 29, and opium in 19. Of the less common poisons two were cases of cyanide, one of iodine, one of caustic soda, one of "phenyle" and one of quinine and ergot. In four cases an unrecognisable alkaloid was extracted from the viscera. In cases of animal poisoning, arsenic was the most commonly found poison, theretin, the active principle of yellow oleander, being next common. The number of cases totalled 42. Of medico-legal cases there were 27 against 21 in the previous year. Two were concerned with the identification of supposed murdered persons from bones which had been discovered. The Chemical Examiner doubts whether, in such cases, it is possible to estimate the height of the person within three inches.

"A case of some interest occurred in which the identity of some hairs was required. A woman was found murdered and grasped in her hand a tuft of hair which she presumably had pulled out of the murderer's head in the struggle which had taken place. A man was arrested on suspicion of having committed the murder and the tuft of hair found with the body and samples of the accused's hair were forwarded to us for an opinion as to whether they were the same. A microscopic examination of the broken ends of the hair found in the corpse's hand showed that the hair had been pulled out and not cut. Although to the naked eye one of the hairs seemed rather more curly, under the microscope, mounted in potash solution, they seemed identical, and to investigate the point further, as curliness is associated with oval cross-section, the two hairs were mounted in paraffin and cross-sections cut for me by the professor of pathology. No differences in the shape of the cross-sections could be found."

This case is still proceeding.

Madras, June 5th.

(FROM OUR OWN CORRESPONDENT.)

Medical Fees and Improved Cost of Living.

THE Ministry of Health has issued a decree addressed to the Chambers of Physicians urging the cutting down of medical fees in accordance with the downward tendency of all prices in the Republic. The Ministry calls attention to the undeniable fall in the prices of food, raw materials, and other articles, and indicates that the medical profession should adapt its fees to this general tendency if the deflation policy of the Government is to succeed. The Chambers of Physicians are asked to take the necessary steps in coöperation with other medical organisations, and report the result to the Ministry as soon as possible. This decree will not arouse much enthusiasm amongst the medical profession; physicians argue that their fees did not keep step with prices in general when the latter were going up, and that, therefore, the present medical fees are still comparatively much below other prices. The price index of medical fees is stated to be at present only 50 per cent. of the index for the average cost of living. In spite of this fact, insurance association fees have already been cut down by 10-15 per cent., and private fees have also automatically declined under pressure of the general economic situation.

Prof. C. Chodounsky.

Prof. Charles Chodounsky recently celebrated his eightieth birthday. He is one of the oldest active physicians in the Republic, and probably the last living pupil of the famous J. E. Purkinje. Chodounsky served as Purkinje's private assistant for a year whilst studying at the University of Prague. After graduation he was forced by financial difficulties to take up private practice, although his real interest lay in research. He found means, however, of carrying on private experimental work, and was also prominent in the work of various medical organisations, being for long the moving spirit of the Scientific Association of Czech Physicians. In 1884 he became associate in balneotherapy in the medical faculty at Prague, and in 1888 he began to lecture also on pharmacology, which then became his chief object of study. In 1890 he

MEDICINE AND THE LAW.

HOUSE-LETTING AND INFECTION: COLLINS *v.* HOPKINS.

IN this important case the question at issue was the extent of the implied warranty by the lessor of a furnished house that it is reasonably fit for the lessee to inhabit, where there has been a case of infectious disease in the house shortly before the lessee's occupation, and with regard to the case before the court, where the disease is pulmonary tuberculosis. Mr. B. M. Collins sued Mrs. E. Hopkins, a widow, for damages for breach of an implied warranty, in letting to him a furnished house at St. Albans, that the house was reasonably fit for habitation. The plaintiff's case was that it was not so fit because the defendant's husband when suffering from pulmonary tuberculosis was living in the house until six weeks before the plaintiff was to occupy it. There was a further alleged ground of claim, that the defendant's agents had expressly warranted that Mr. Hopkins was not suffering from consumption, but Mr. Justice McCardie, in his judgment, dealt only with the first point, and the agents denied having made the statements attributed to them.

In February, 1922, Mr. Hopkins was found to be suffering from tuberculosis. He was treated in a sanatorium, but was at home in July and again at the end of August till Sept. 11th, when he went to Switzerland, where he died in December. The agreement to let was made on Oct. 14th, the tenant's occupancy to begin on Oct. 26th. The plaintiff heard of the nature of Mr. Hopkins's illness on the day after he entered the house, and at once repudiated the agreement and left it. He claimed damages, including the return of a first instalment of rent (£88).

Medical evidence for the plaintiff was given by Dr. W. J. Fenton, who said that it would not be safe to take a furnished house as described, unless there had been thorough disinfection of walls and floors and fumigation under skilled supervision by the medical officer of health. In cross-examination he admitted that he knew of no case of infection proved to have arisen from the presence of a person suffering from tuberculosis in a house six weeks before a second person inhabited it. For the defence Dr. S. Vere Pearson, who had treated Mr. Hopkins at Mundesley Sanatorium, described his case, and expressed the opinion that there was no risk in the plaintiff occupying the house on Oct. 26th. He had never heard of infection in such circumstances as those described, and said that there was no recorded instance of tuberculous infection taking place in premises which an affected person had lived in and left. Dr. E. H. Lipscomb described his treatment of Mr. Hopkins at St. Albans. He had omitted to notify the case, and had not thought it necessary that the house should be fumigated. Dr. A. L. Punch was of opinion that there would have been no danger, as in the circumstances described the life of the bacillus would not have been more than a week or two. Evidence was given by the defendant and the agent who let the house.

Mr. Justice McCardie, in a considered judgment, reviewed the law relating to the subject, and had no doubt that "an appreciable measure of actual risk justifies the tenant in throwing up his contract. A man should not be called on to expose his wife and children or himself to peril." Among the matters to be considered were the nature of the disease, the degree and persistence of its infectivity, the date when the sufferer lived in the house, and the steps taken to prevent infection. In dealing with the case before him his lordship referred to the defendant as an unsatisfactory witness, who had admitted that if she had been asked what was the matter with her husband she would have answered "slight lung trouble only," and he was of opinion that the house had been left in a very dirty state for the plaintiff to go into. He also referred to the deceased as having gone to the city and about his ordinary business when warned that he might infect others. He referred to Dr. Lipscomb's evidence as to his not having notified the disease through an oversight, and regretted that no medical man should have supervised the disinfection of a house about to be let furnished.

His lordship's final summing up of his own conclusions indicate his application of the law to the facts of the particular case: (1) "I am not satisfied that the house and its contents were free from tubercle bacilli on Oct. 26th, 1922; (2) I am satisfied that there was a substantial risk that the house and its contents were so infected with bacilli on Oct. 26th as to constitute an actual danger to the plaintiff and his household; (3) while recognising the difficulties of inference on the point I should hold, if necessary, that in fact the house and its contents were so infected with tubercle bacilli on Oct. 26th as to render it unsafe for occupation. I therefore rule that it was not reasonably fit for habitation. It follows that the plaintiff was entitled to renounce the tenancy and quit the house; also that he is entitled to damages." His lordship accordingly gave judgment for the plaintiff for £130 with costs.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Education in Madras Presidency, 1917–1922.

THE report of the Director of Public Instruction for the five years ending March 31st, 1922, on the state and progress of education in Madras Presidency has recently been issued by Government. Among the items of importance to the medical profession are the following:—

(1) *Medical Inspection of School Children.*—In 1920 a system of grants-in-aid for medical inspection in aided and public schools was introduced, and over 200 schools were inspected by approved medical officers and participated in the general scheme for grants-in-aid for this work. It was originally proposed to appoint three sub-assistant surgeons to inspect Government schools and to correlate and direct the work of the other medical inspectors, but this scheme has been held in abeyance. Inspection has not yet been conducted in accordance with settled principles, universally applied; but there can be no doubt as to the urgent necessity for such inspection. Several aided secondary schools appointed medical inspectors and received grants, and some other schools, though not receiving Government grants, conducted medical inspections. So far no medical inspection has been undertaken in Government schools.

(2) *Medical College.*—The subordinate teaching staff of the Medical College has been reorganised and the system under which certain assistant surgeons were detailed for college work and given no hospital duties, while those attached to the hospitals and assisting in imparting clinical instruction to students were not given any teaching allowance, was discontinued; all assistant surgeons actually engaged in instruction, whether in the College or in the hospitals, were appointed assistants to the professors concerned and given hospital as well as teaching work and uniform rates of allowances. In February, 1920, the Government of Madras sanctioned the proposal to institute a course of training for six months in dental surgery for civil assistant surgeons and senior sub-assistant surgeons not exceeding five at a time. The first course was held in 1920 and proved a success. Post-graduate courses for civil assistant surgeons were also begun in 1920. In December, 1921, the Government of Madras directed that the students of the College should be trained in squad, company, and physical drill during their third year, and in stretcher drill and first-aid during their fourth year.

(3) *Medical Schools.*—The medical schools at Calicut, Vizagapatam, Tanjore, and Rayapuram worked throughout the period under review. In July, 1918, a new school was opened at Madura with

a staff of one superintendent and four lecturers. The strength of the schools has continued to increase. During the years 1917 to 1922 the strength of the Rayapuram school increased from 310 to 569 and that of the Tanjore school from 148 to 276. The total strength of schools in 1921 was 1262 as against 662 in 1917. Accommodation and equipment are generally unsatisfactory: the provision of hostels has become an urgent necessity for all the schools.

(4) *Physical Education and Hygiene.*—The last quinquennial report stated that "the weak point about physical education is that those who stand most in need of physical culture get least of it." This state of affairs is passing away; all inspectors report on the advance made during the last five years. Scout troops have only been really organised in Madras since 1917, but by 1920 there were 280 scout troops and packs with a total of 500 officers and over 6000 scouts. In 1921 Government approved a new syllabus on hygiene for Forms I. to III.; this syllabus was translated into the principal vernaculars, and was adopted in all middle and secondary schools.

Beri-beri in Madras Presidency.

In 1918–20 Colonel R. McCarrison, I.M.S., at the instance of the Indian Research Fund Association, undertook an investigation into beri-beri. As a result of his inquiries it was found that in Madras Presidency the disease is confined to a narrow tract on the east coast comprising the districts of Ganjam, Vizagapatam, Godaveri, Kistna, Guntur, and Nellore. No cases of beri-beri have been reported from districts lying outside this strip of coast except for a few in Vellore and in Bellary Jail. The disease attains its maximum degree of endemicity in the Kistna district, lying between the Kistna and Godaveri rivers, and is particularly prevalent in the neighbourhood of the left bank of the Kistna. At the Fourth Congress of the Far Eastern Association of Tropical Medicine held in 1921 it was recommended that governments concerned should take action to discourage the case of milled rice which contains less than the standard minimum of four-tenths of 1 per cent. of P_2O_5. The Congress also recommended the appointment of a commission, to which each country would be asked to send a delegate, which would make recommendations as to the best methods of bringing beri-beri under control. Colonel McCarrison considered that the provinces of Madras, Burma, and Bengal were sufficiently affected to require legislation; in anticipation of such action a brief memorandum on the subject of the causes of beri-beri has been prepared by him in consultation with the Director of Public Health, and this has recently been issued by the Government of Madras for propaganda purposes, translations having been made into the local vernaculars of the districts affected. Legislation for milled rice may be impracticable under present conditions, and it seems more reasonable to diffuse knowledge of the disease and its prevention than to interfere with mill-owners and their machinery.

Chemical Examiner's Report for 1922.

Major C. Newcomb's report as usual contains a number of interesting details. The total number of cases and articles examined was 3824 against 3952 in 1921. Human poisoning cases numbered 220, and stain cases 399. He says:—

> "The regularity throughout the year with which the murder cases are sent to us is striking. One would expect, I think, some seasonal variation in their numbers or some indication of the 'waves of crime' of which one reads from time to time in the newspapers. . . . So far as the statistics of this department show, there is no murder season in the Madras Presidency, and waves of crime if they exist must be very choppy ones."

Of the 220 cases of suspected human poisoning, 108 showed poison, giving a positive percentage of 49·1 as compared with 40·6 in 1921. The chemical examiner, however, regrets in this connexion that more time is not available for experimental use of new toxicological methods. Of the 108 human cases in which poison was detected, mercury was found in 32 cases, arsenic in 29, and opium in 19. Of the less common poisons two were cases of cyanide, one of iodine, one of caustic soda, one of "phenyle" and one of quinine and ergot. In four cases an unrecognisable alkaloid was extracted from the viscera. In cases of animal poisoning, arsenic was the most commonly found poison, theretin, the active principle of yellow oleander, being next common. The number of cases totalled 42. Of medico-legal cases there were 27 against 21 in the previous year. Two were concerned with the identification of supposed murdered persons from bones which had been discovered. The Chemical Examiner doubts whether, in such cases, it is possible to estimate the height of the person within three inches.

> "A case of some interest occurred in which the identity of some hairs was required. A woman was found murdered and grasped in her hand a tuft of hair which she presumably had pulled out of the murderer's head in the struggle which had taken place. A man was arrested on suspicion of having committed the murder and the tuft of hair found with the body and samples of the accused's hair were forwarded to us for an opinion as to whether they were the same. A microscopic examination of the broken ends of the hair found in the corpse's hand showed that the hair had been pulled out and not cut. Medical Fees and Improved Cost of Living.

THE Ministry of Health has issued a decree addressed to the Chambers of Physicians urging the cutting down of medical fees in accordance with the downward tendency of all prices in the Republic. The Ministry calls attention to the undeniable fall in the prices of food, raw materials, and other articles, and indicates that the medical profession should adapt its fees to this general tendency if the deflation policy of the Government is to succeed. The Chambers of Physicians are asked to take the necessary steps in coöperation with other medical organisations, and report the result to the Ministry as soon as possible. This decree will not arouse much enthusiasm amongst the medical profession; physicians argue that their fees did not keep step with prices in general when the latter were going up, and that, therefore, the present medical fees are still comparatively much below other prices. The price index of medical fees is stated to be at present only 50 per cent. of the index for the average cost of living. In spite of this fact, insurance association fees have already been cut down by 10-15 per cent., and private fees have also automatically declined under pressure of the general economic situation.

Prof. C. Chodounsky.

Prof. Charles Chodounsky recently celebrated his eightieth birthday. He is one of the oldest active physicians in the Republic, and probably the last living pupil of the famous J. E. Purkinje. Chodounsky served as Purkinje's private assistant for a year whilst studying at the University of Prague. After graduation he was forced by financial difficulties to take up private practice, although his real interest lay in research. He found means, however, of carrying on private experimental work, and was also prominent in the work of various medical organisations, being for long the moving spirit of the Scientific Association of Czech Physicians. In 1884 he became associate in balneotherapy in the medical faculty at Prague, and in 1888 he began to lecture also on pharmacology, which then became his chief object of study. In 1890 he published his "Theoretical Pharmacology," in 1896 a "Programme of Toxicology," and in 1920 a "Text-book of Pharmacology." He also published a great number of lesser studies on different problems of pharmacology, and a long series of popular articles on public health topics. He is one of the founders of Czech medical terminology. Formerly a distinguished Alpinist and sportsman, Prof. Chodounsky retains excellent health, and although he had retired from University work shortly before the war, he went to Brno (Brünn) when the new medical faculty was created there after the establishment of the Czecho-Slovak Republic, and organised the institute of pharmacology, materially assisting in the organisation of the whole faculty, and remaining at the head of the institute until he had trained his successor. He has now entered honourable retirement for the second time.

First Czecho-Slovak Tuberculosis Congress.

In May took place the first Czecho-Slovak National Congress against Tuberculosis, organised by the Society for Research in Tuberculosis, and preceded by the annual meeting of the Masaryk Antituberculosis League. There were over 350 medical men present, and 120 papers were read. The three sessions of the Congress were devoted to clinical and theoretical questions, social problems, and veterinary problems respectively. Important resolutions were adopted based largely on papers read at the Congress, and relating to the creation of special institutes for research and instruction, to the establishment in general hospitals of pavilions for advanced cases of tuberculosis in order to relieve the pressure upon sanatoriums, and to compulsory medical examination of persons who want to marry. The importance of popular public health education, especially for children, was also emphasised, and the Government was asked to study the question of the early immunisation of children. School hygiene, housing and factory inspection, and Government support of necessitous tuberculous persons were also the subjects of resolutions, together with inspection of meat and milk, and the appointment of a permanent committee for the study of tuberculosis in cattle.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The following are the principal health statistics of a number of towns and urban districts for the year 1922:—

Name of town.	Estimated population (mid-year).	Birth-rate.	Death-rates per 1000 of population. All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Death-rates per 1000 births. Infant mortality. Legit.	Illegit.	Maternal mort. in childbirth.
Coventry C. ..	129,000	18·9	10·6	1·2	1·0	2·2	70	78	2·5
Grimsby C.B. ..	83,600	24·0	13·1	1·4	1·3	2·6	91	124	3·5
Eastbourne C.B.	53,700	13·7	10·9	0·7	1·6	1·8	45	37	—
Colchester B. ..	43,740	18·0	11·9	1·1	1·4	1·2	60	79	1·3
Poole B.	43,250	20·0	14·4	1·5	1·4	2·3	77	132	4·6
Swindon B. ..	55,680	19·0	12·2	1·3	1·0	2·8	58	122	0·9
Maidstone B. ..	38,300	18·0	11·1	1·0	—	—	53	114	2·9
Hyde B.	34,100	16·5	12·7	1·1	1·3	3·0	65	33	0·0
Barry U.D. ..	39,310	23·6	11·6	1·1	0·9	2·6	84	94	3·2
Beckenham U.D.	33,160	16·0	10·7	0·8	1·5	2·6	55	50	0·0

C. = city. C.B. = county borough. B. = borough. U.D. = urban district.

Coventry.

Dr. E. H. Snell submits a table showing that the mean age at death has gradually increased from 35·1 in 1895 to 45·4 in 1922; a chart showing that since 1881 the birth-rate has come down from the neighbourhood of 35 to about 20, and the death-rate from 20 to 10; and another chart showing the drop in infantile mortality in the present century from 150 to 70. Attention is drawn to the need for covering the Spon End tank, through which passes about one-third of the city's water-supply. The housing question is still urgent. Houses closed before the war have had to be reopened and remain occupied; only gross cases of overcrowding can be dealt with, and Dr. Snell gives the details of 10 very gross cases. He also refers to the lessening frequency of rickets in the out-patient rooms of large hospitals. Of 28 notified cases of ophthalmia neonatorum, 25 made complete recoveries, 2 partial recoveries, and 1 is totally blind.

The school dentists think that the practice of charging a shilling fee for dental treatment is an obstacle. Only 1660 children out of 3338 referred for treatment actually received treatment. The total fees paid in 1922 only amounted to £68. The Corley Camp open-air school for 16 children did good service. Dr. A. H. Newton mentions the case of two of the children, who continually suffered from colds and bronchitis at home, and spent the summer at the camp, going about without shoes and stockings, without a suspicion of colds or bronchitis. The open-air class at Centaur-road school also did well. Miss E. K. Brown, the organiser of physical training, gives an interesting report of her work. She now has 52 elementary schools, one special school, and two open-air classes under her supervision. A daily physical training lesson and deep-breathing exercises in the fresh air, folk-dancing, and organised games are some of the features. Special attention is given to swimming; at the swimming gala 23 first-class certificates were awarded to girls and only 5 to boys. Miss Brown finds a great deal of mouth-breathing is simply due to long-standing neglect to use a handkerchief effectively.

Dr. Newton reports unfavourably on the way meals are supplied at the municipal restaurant. He thinks there might be more variety, more green vegetables, and more fat, but he is chiefly concerned about the service. A plateful of each course is put out on the table ready for each child coming in. The child finishes the meal in just over five minutes. One is not surprised, therefore, to hear that there have been statements from parents that the meals make the children sick. The only cutlery supplied is one spoon for both courses. Such meals can hardly be called educational in table manners.

Grimsby.

Dr. B. C. Stevens reports among the needs of Grimsby—provision for advanced consumptives (the borough already owns the site on which to build a 30-bed hospital), a maternity home, and an infants' hospital. The V.D. clinic, which has been removed from the Grimsby and District Hospital to more commodious premises in Queen-street, is proving increasingly useful. It is coöperating well with the ante-natal clinic and being used by seamen in a satisfactory manner. Dr. Stevens emphasises the need for the better protection of food from contamination, and especially advocates the wrapping of bread in waxed paper before it leaves the bakery, a method which has the additional advantage of keeping the loaf fresh. He also draws attention to the present dirty methods of handling meat, and points out that imported meat is better protected than the home product.

Eastbourne.

Dr. W. G. Willoughby points out that the most serious adverse factor in public health matters is the want of adequate housing accommodation. "Private enterprise in building, seriously injured by well-meant but pernicious legislation in 1907–10, was finished off by the war. Municipal housing is a necessity because the private owner does not like families with children and does not mind if a good tenant is an old resident of Eastbourne or not. In letting municipal houses preference is given to large families, and length of residence in Eastbourne and war service are taken into consideration. Apart from non-residents, families without children, and families with fair accommodation, there are about 400 families needing houses. This number includes families in hut tenements, which ought to be abandoned as soon as possible." Of the four genuine cases of enteric fever notified, three are said to have acquired the infection elsewhere. A fifth notified case, proved to be acute miliary tuberculosis, gave a positive Widal reaction, evidently the result of inoculation during the war.

At the tuberculosis dispensary Dr. W. Muir Smith continues to use tuberculin in selected cases with satisfactory results. The municipal midwife, who acts as a health visitor when not engaged in obstetrical work, attended 52 confinements. The full fee, 25*s*., for her services was paid in 39 cases. Eleven mothers were provided with dentures, eight free of cost.

Colchester.

Dr. W. F. Corfield draws attention to the decline in tuberculosis and the increase in cancer. He again points out the pressing need for more houses, and states that habitations are still in use that should not be tolerated. There is a small revival of private building. An outbreak of diphtheria at the Essex County Hospital was promptly stamped out by "swabbing" and the isolation of 12 positive contacts, over and above the 13 cases of the disease. The long-tubed bottle, after a short return to Colchester, has again been suppressed, and Dr. Corfield would like to see it prohibited by law.

Poole.

Dr. R. J. Maule Horne tells us there are signs that Poole is coming into its own as one of the most picturesque health-resorts on the South Coast, and that for natural beauty its harbour stands comparison with Sydney or Rio de Janeiro. The water is purified by chlorination and additional pumping is being installed as a safeguard against a very dry season. Cesspools are being gradually replaced by sewers; a table shows that there were still 379 in existence last year. Dr. Horne wants a modern refuse plant and condemns the three tips as uneconomical and bad public health. "Fires, fumes, flies, fungi, and four-footed fomites are the legacy." Of the 145 new houses completed during the year, 100 are occupied by new residents, so that little has been done to relieve the shortage in the congested districts. During Health Week oral sepsis was wisely chosen as the special theme.

Swindon.

Dr. Dunstan Brewer reports that influenza, as in other towns, was epidemic in the beginning of the year. A severe form of whooping-cough, with pneumonia as a common complication, was also prevalent at the same period. The mortality, owing to overcrowding, was very high among the home-treated cases, and in future an endeavour will be made to provide accommodation for such cases in the fever hospital. The opening of the maternity home in July and the establishment thereat of an ante-natal clinic has supplied a long recognised need. Anxiety as to the water-supply was relieved by the wet summer, and in the meantime progress with the new adits at Ogbourne has provided for the future.

The corporation have completed 90 new houses outside the borough and private enterprise 24 within, but this has not relieved overcrowding, when the natural increase of the population is taken into consideration. Nevertheless, as the report of the sanitary inspector puts it, the outlook in Swindon is much better than in some towns. Dr. Brewer considers that the class which has suffered most is that of newly married couples in moderate circumstances. The majority of first babies are born to couples living in rooms, frequently in a single room. Families, as they increase in size, cannot move to larger houses, as formerly. Swindon's most urgent need is a hospital of about 150 beds for surgical and medical cases. The present accommodation is a private 12-bed hospital belonging to the G.W.R. Medical Fund Society, and a 32-bed cottage hospital. Swindon has grown very rapidly and used to depend upon the London hospitals.

Maidstone.

Dr. C. P. Oliver reports no extraordinary causes of sickness or invalidity during the year. Analytical reports of the water have been satisfactory. The gathering-grounds and reservoirs continue to be patrolled daily by an employee of the Water Company, and have been inspected by Dr. Oliver in company with Prof. J. Eyre, Dr. A. Greenwood (County M.O.H.), and Mr. Ware, the engineer, and invariably found to be in a satisfactory condition.

Hyde.

Dr. Nicolas Gebbie, who took over the duties of M.O.H. from Dr. J. Bennett on Feb. 6th, 1922, reports that except for an outbreak of measles in the summer the borough has been fairly free from infectious diseases. Only about 20 per cent. of the sanitary conveniences are w.c.'s with cistern flush, 65 per cent. being w.c.'s with hand or waste-water flush, and 15 per cent. pails or privy middens. The 1500 ashpits in the borough create a serious nuisance. Warnings have been issued with regard to smoke from factory chimneys, but no prosecutions were undertaken.

Overcrowding is serious, and in some parts of the borough there are three and four families living in a four-roomed cottage. Indiscriminate mixing of the sexes at all ages results. "Under these circumstances," says Dr. Gebbie, "we cannot hope for a strong race, physically, mentally, or morally." One of the pavilions at the new fever hospital forms part of the county tuberculosis scheme, and admits advanced cases of consumption. Owing to unemployment, fewer mothers have been working at the mills, and Dr. Gebbie thinks the loss to the family income was more than compensated for by the greater care taken of the children and the increased facilities for breast-feeding.

Barry Urban District and Port.

Dr. Percy W. Kent describes the small outbreak of small-pox which occurred in Barry in 1922. Two sailors, feeling ill, left their ship in London and arrived in Barry on the morning of Oct. 5th. (During the voyage there had been two seamen down with illnesses diagnosed as chicken-pox.) One of the sailors infected an unvaccinated boy, aged 4 years, who was notified as small-pox and died from a confluent attack. The notification was followed by the discovery that both sailors and the aunt of the boy were suffering from modified small-pox. All three had been vaccinated in infancy, and one of them revaccinated at 14 years of age. Prompt measures were taken as to the supervision and vaccination of contacts, and no further case occurred. Subsequently the captain of the ship was summoned by the London Port Sanitary Authority for giving incomplete information and fined £50. Another case of small-pox arrived in the port from Lisbon in July, and was removed to the small-pox hospital.

The urban district council manages an accident and surgical hospital, with a medical staff consisting of the M.O.H. as superintendent, a surgeon, three assistant surgeons, and a radiographer. Dr. G. H. Winch, the V.D. medical officer, states that the clinic, opened in October, 1921, in the same building as the maternity and child welfare and school clinics, is ideally situated, that the patients are keen and regular in their attendance, and that a large number of seamen are treated. In his opinion provision for the treatment of seamen is, as a rule, not properly organised. Dr. Kent gives evidence to show that the water-supply is not safe, and this matter is receiving the careful attention of the council.

Beckenham Urban District.

Dr. J. M. Clements reports that the urban districts of Beckenham and Penge have provided a joint maternity home, the midwives from which attend some extern cases, while an arrangement has been made with the two certified midwives practising in the district to attend other extern cases. In addition to these two midwives there are a number of unqualified persons who go out as monthly nurses under the supervision of doctors in charge of the cases. Dr. Clements is anxious for a more precise definition of the degree of supervision to be given by the doctor in charge of such cases. He also complains of the unsatisfactory arrangement by which the district council has everything to do for mothers and infants except the supervision of the midwives, which is carried out by the county council, although the work of the midwives is indissolubly bound up with the whole scheme of maternity and child welfare.

The school clinic needs extension, partly for the purpose of housing the dental clinic under the same roof. The school dentist, Mr. Robert A. Waters, shows that of 2298 children referred for treatment, 1788, or 78 per cent., were actually treated. Of the remaining 22 per cent., 18 refused treatment, two failed to keep appointments, and two said they would get private treatment, but generally failed to do so. The 18 per cent. definite refusals were sometimes due to the attitude of the parents, sometimes to the attitude of the older children, who refuse to attend even at the wish of their parents.

SCHOOL MEDICAL SERVICE.

Derbyshire.

During the year 26,744 children were medically examined, 26,389 of these coming under the routine age-groups. Of the latter 6702 were referred for treatment, and during the year 2505 children received treatment for eye trouble and 3605 for ear disease. Operations for diseased tonsils and adenoids were performed upon 1155 children; these are excluded from school for two weeks after operation. 151 cases of ringworm were treated by means of X rays; 19,936 dental extractions and 13,526 dental fillings were performed. Dr. Sidney Barwise demonstrates that the young boys and girls in Derbyshire are taller and heavier than the average of the same class in England and Wales, but in the later ages the advantage is not maintained. Examination of the secondary school children reveals the fact that postural deformities with the exception of flat-foot are much less common in boys than in girls. Of 816 boys examined, 54 had some degree of flat-foot; 2 per cent. had colour-blindness. Of 1803 girls examined in the secondary schools 270 had enlarged or septic tonsils and adenoids. Goitre was present in 194. In the more marked cases it was fairly easy to persuade the parents to have the condition treated, but in far too many of the milder cases it is still regarded as just Derbyshire neck, something that runs in the family. Tables are given showing the personal equation of the doctor in discovering and recording defects; the percentage of children referred for all conditions varying in different doctors' districts from 33·6 to 11·5 per cent. During the year 861 children were excluded from school, 105 because they were verminous, 755 for medical reasons, 287 of these being on account of tuberculosis. There were 17 permanent exclusions from school, 7 of them being on account of mental condition, 2 for epilepsy, and 2 for defective vision. Dr. Mary Gallagher gives the results of 983 cases of enlarged tonsils and adenoids upon which she operated. In one half of these cases the condition had caused secondary complications such as suppurating middle-ear disease or chronic catarrh of the middle ear with deafness, chronic inflammation and discharge from the nose. In a considerable number of cases operation had to be deferred owing to treatment for anæmia, septic teeth, &c., having to be carried out. In one case the child had to be treated for six months before she was fit for operation. Of the 983 cases operated on, 890, or 90 per cent., were discharged cured and 83 improved. In ten cases there was no improvement. In several cases operations were performed on children who had already been operated on with the guillotine—that is, a piece of the tonsil had been sliced off—and after a short time the symptoms had unfortunately recurred. Dr. Gallagher states that the cardiac condition of 30 children was such that the operation was performed without an anæsthetic. We should consider it doubtful, however, whether such a procedure would be likely to do less damage than an operation under carefully administered anæsthesia.

The school dentist submits an interesting report. He finds that 80 per cent. of the children inspected were referred for treatment, and 20 per cent. actually treated. He insists that any propaganda for the prevention of caries in children must depend on the teachers.

The Services.

ROYAL ARMY MEDICAL CORPS.

An examination for not fewer than 20 commissions in the Royal Army Medical Corps will be held in London on August 1st. Those who intend to compete should lodge their applications with the Secretary of the War Office not later than July 20th. The presence of candidates will be required in London from July 30th. A full statement of the duties and emoluments of the service will be furnished to prospective candidates on written application to the Secretary (A.M.D.1), War Office, Whitehall, S.W. 1.

Maj. A. H. Bond, *from the half-pay list, is restored to the* estbt.

Capt. R. Stowers retires, receiving a gratuity.

Capt. K. Masson retires on account of ill-health.

Temp. Hon. Maj. J. L. Dickie relinquishes his commn. and retains the hon. rank of Maj.

Temp. Capt. D. S. Taylor relinquishes the acting rank of Maj.

The undermentioned *temp. Capts. relinquish* their commissions and *retain the rank* of Capt.: T. A. Rothwell, S. Herbert (on account of ill-health contracted on active service), and W. J. E. Stuttaford.

TERRITORIAL ARMY.

Capt. H. J. Davidson retires, receiving a gratuity.

General List: Maj. V. H. Wardle (late R.A.M.C., T.A.) to be Capt. and relinquishes the rank of Maj.

General Hospitals: Lt.-Col. W. E. Hume and Capt. (Bt. Maj.) R. E. Kelly relinquish their commns. and are granted the rank of Col.

Sanitary Companies: Capt. R. J. S. McDowan relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY RESERVE.

Capt. J. Derham-Reid *relinquishes his* commn. and is granted the *rank of Maj.*

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdrs. W. L. Martin and A. L. Hewitt to be Surg.-Capts.

ROYAL AIR FORCE.

Squadron Leader A. S. Glynn *to* be Wing Commander.

Flight-Lieutenants R. J. Aherne, P. H. Young, and P. T. Rutherford to be Squadron Leaders.

DEATHS IN THE SERVICES.

Surg.-General Sir Benjamin Simpson, C.B., K.C.I.E., late Surgeon-General and Sanitary Commissioner with the Government of India, died at his residence in London on June 27th. Born in 1831, he qualified with the M.R.C.S. in 1852 and graduated M.D. at Aberdeen in the following year, when he entered the Indian Medical Department. After serving as civil surgeon and on special duty in various parts of India, he was appointed guardian to the Maharajah of Kuch Behar during his visit to Europe in 1878, and in 1881 was appointed Deputy Surgeon-General with the S. Afghanistan Field Force. In 1882 he became Sanitary Commissioner to the Central Provinces, subsequently serving as Surgeon-General in the Punjab and in Bengal. He received the C.B. in 1859 and the K.C.I.E. in 1887.

HARROGATE SPA: NEW FACILITIES OF TRAVEL.

At the invitation of the Mayor and Corporation a number of medical men, including representatives of the *British Medical Journal* and of *The Lancet*, paid a week-end visit to Harrogate on June 30th and July 1st. The occasion was the inauguration of a new Pullman Car service, arranged jointly by the London and North-Eastern Railway Company and the Pullman Car Company, Ltd. The new service of trains is to commence on Monday, July 9th, making the journey from King's Cross to Harrogate, or vice versa, in precisely four hours, with a non-stop run between London and Leeds. Each train will consist of two first-class and four third-class specially-built cars, comfortably furnished and tastefully decorated, with arrangements for serving meals to 180 passengers during the journey and adequate lavatory accommodation. Judging by the trial trip, in which many important railway officials took part, the facilities provided leave nothing to be desired.

The medical men making up the party were as follows: Dr. John Adams, Dr. L. D. Bailey, Dr. D. M. Barcroft, Dr. W. Langdon Brown, Sir Bruce Bruce-Porter, Dr. A. G. Buchanan, Dr. H. S. Buchanan, Dr. A. T. Davies, Dr. Henry Dutch, Dr. H. A. Ellis, Dr. R. Fortescue Fox, Dr. E. P. Furber, Dr. A. T. Bulkeley Gavin, Dr. Philip Hamill, Dr. W. D. Kirkwood, Dr. H. Moreland McCrea, Dr. B. Myers, Dr. H. H. Sanguinetti, Dr. W. M. Crawford Watson, Dr. Arthur Westerman, Dr. E. C. Young.

On Saturday afternoon a visit was paid to the Royal Bath Hospital and Ransom Convalescent Home, which is designed for patients unable to afford private treatment in Harrogate, suffering from skin diseases, rheumatic and kindred diseases, disorders of the liver, gout, locomotor ataxy, and lead poisoning. Patients are now charged 10*s*. 6*d*. per week towards the cost of their board, unless specially exempted. Admission is on the recommendation of annual subscribers, life governors, or contributing bodies. Visitors were received by the Chairman, Mr. C. A. Rhodes, J.P., and shown round the hospital by one or other of the six physicians.

Fig. 1.—*Harrogate in Summer: the Valley Gardens.*

The visitors were entertained at the Majestic Hotel, where the Deputy Mayor presided at a public dinner on Saturday evening. "The Town of Harrogate" was proposed by Mr. R. L. Wedgwood, Chief General Manager of the L. & N. E. Railway, who spoke of the growth of Harrogate as a health resort during two generations without any glamour of historical record, and foreshadowing further improvements to come. The Deputy Mayor, Mr. Alderman J. Sheffield, having replied, the toast of "Our Guests" was proposed by Sir A. Ernest Bain, Chairman of the Wells and Baths and Publicity Committee. Sir Davison Dalziel responded for the Pullman Car Company, Dr. R. Fortescue Fox for the medical guests. Dr. Fox spoke of spas as a national asset, expressing his personal belief in the curative virtues of British waters and British climate, each spa having its own individual character and value. In the long run success would be achieved by each spa developing its own natural resources. Britain was happy in possessing the most tonic spas of the world, which would, if properly known, attract multitudes of foreigners. Utilisation of these natural products was, he said, a necessity for our present stage of civilisation, with its large floating population of tired people. He hoped soon to see the long delayed recognition of spa treatment by State and universities.

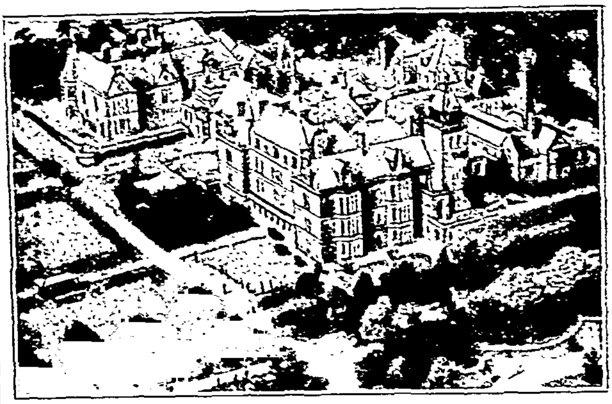

Fig. 2.—*The Royal Bath Hospital, viewed from the air.*

Dr. David Brown, speaking for the Harrogate Medical Society, emphasised four points in connexion with the treatment. In the first place, Harrogate made provision for persons of various means. For a hundred years the Royal Bath Hospital had provided 150 beds for the service of the poor, with an endowment of £2,200 a year and supported to the extent of six-sevenths by the visitor element. This hospital remained open all the year round, drew its patients from all parts of England, and treated 2000 patients annually. The honorary staff numbered 17 individuals and work of clinical importance and investigation was proceeding. He ventured to say that if patients of the rheumatic group reached them early enough, the bed-ridden cripple might be abolished altogether. In the second place, arrangements were in force to enable the "new poor" (with an income of under £600 a year) to obtain a combined and inclusive investigation of their case at a cost not exceeding 15 guineas. Thirdly, a school of balneology had been set up for bath attendants, who numbered in Harrogate over 200, no departmental instructor now being appointed who had not had a course of instruction lasting over two years. And lastly, much thought was being given to the scientific care of the baths and waters, an analytical chemist—a permanent servant of the Corporation—being concerned in working out the basal problems for the rationalisation of approved balneological measures.

The company attended a special concert at the Royal Hall on Saturday evening. On Sunday morning followed an inspection of the Royal Baths, closed to the public for the occasion, guests being asked to make personal use of any of the baths, of which 78 scheduled varieties are set out in the list of treatments for the current season. These are divided into three classes: (1) under the heading Balneological being included many varieties of saline-sulphur bath and douche, Nauheim, Turkish, Russian, and Berthollet baths, massage-douche on the Aix system, Vichy douche, peat baths and packs, and many others; (2) under the heading Accessory Treatments being included inhalation treatment, liver packs, paraffin wax baths, and remedial and mechanical exercises; while (3) Electrical Treatments comprise high frequency, cataphoresis, diathermy, and other currents.

Beckenham Urban District.

Dr. J. M. Clements reports that the urban districts of Beckenham and Penge have provided a joint maternity home, the midwives from which attend some extern cases, while an arrangement has been made with the two certified midwives practising in the district to attend other extern cases. In addition to these two midwives there are a number of unqualified persons who go out as monthly nurses under the supervision of doctors in charge of the cases. Dr. Clements is anxious for a more precise definition of the degree of supervision to be given by the doctor in charge of such cases. He also complains of the unsatisfactory arrangement by which the district council has everything to do for mothers and infants except the supervision of the midwives, which is carried out by the county council, although the work of the midwives is indissolubly bound up with the whole scheme of maternity and child welfare.

The school clinic needs extension, partly for the purpose of housing the dental clinic under the same roof. The school dentist, Mr. Robert A. Waters, shows that of 2298 children referred for treatment, 1788, or 78 per cent., were actually treated. Of the remaining 22 per cent., 18 refused treatment, two failed to keep appointments, and two said they would get private treatment, but generally failed to do so. The 18 per cent. definite refusals were sometimes due to the attitude of the parents, sometimes to the attitude of the older children, who refuse to attend even at the wish of their parents.

SCHOOL MEDICAL SERVICE.

Derbyshire.

During the year 26,744 children were medically examined, 26,389 of these coming under the routine age-groups. Of the latter 6702 were referred for treatment, and during the year 2505 children received treatment for eye trouble and 3605 for ear disease. *Operations* for diseased tonsils and adenoids were performed upon 1155 children; these are excluded from school for two weeks after operation. 151 cases of ringworm were treated by means of X rays; 19,936 dental extractions and 13,526 dental fillings were performed. Dr. Sidney Barwise demonstrates that the young boys and girls in Derbyshire are taller and heavier than the average of the same class in England and Wales, but in the later ages the advantage is not maintained. Examination of the secondary school children reveals the fact that postural deformities with the exception of flat-foot are much less common in boys than in girls. Of 816 boys examined, 54 had some degree of flat-foot; 2 per cent. had colour-blindness. Of 1803 girls examined in the secondary schools 270 had enlarged or septic tonsils and adenoids. Goitre was present in 194. In the more marked cases it was fairly easy to persuade the parents to have the condition treated, but in far too many of the milder cases it is still regarded as just Derbyshire neck, something that runs in the family. DEATHS IN THE SERVICES.

Surg.-General Sir Benjamin Simpson, C.B., K.C.I.E., late Sanitary Commissioner with the Government of India, died at his residence in London on June 27th. Born in 1831, he qualified with the M.R.C.S. in 1852 and graduated M.D. at Aberdeen in the following year, when he entered the Indian Medical Department. After serving as civil surgeon and on special duty in various parts of India, he was appointed guardian to the Maharajah of Kuch Behar during his visit to Europe in 1878, and in 1881 was appointed Deputy Surgeon-General with the S. Afghanistan Field Force. In 1882 he became Sanitary Commissioner to the Central Provinces, subsequently serving as Surgeon-General in the Punjab and in Bengal. He received the C.B. in 1859 and the K.C.I.E. in 1887.

of the pancreas in any case of diabetes, and also to recognise, or exclude, most of the other causes known to give rise to hyperglycæmia. Even if we limit the term diabetes mellitus to those instances in which disease of the pancreas can be shown to exist in this way however, we are still far from being able to answer the question in point with precision, although we are nearer doing so, for it would seem that the progress of the disease can be stayed, and permanent improvement be brought about, either by alimentary rest or insulin, when the hyperglycæmia is dependent entirely, or largely, upon a functional deficiency of the internal secretion of the pancreas, also that its progress, under suitable dietary restrictions, is slow when the condition arises as a result of sclerosis of the gland so that the state of the patient is analogous to that of a partly de-pancreatised dog, but that when the deficiency is brought about by an attempt to control, and compensate for, some other cause interfering with carbohydrate metabolism no treatment directed toward the pancreatic factor alone is of more than temporary benefit.

The only answer, therefore, which can at present be given to the question under discussion in my opinion, is that, since diabetes mellitus is not a disease but a symptom-complex arising from a variety of causes, each case is more or less a law unto itself, and whether it will progress or not depends upon the accuracy with which it is diagnosed and how far suitable methods of treatment are applied to the particular conditions discovered.

I am, Sir, yours faithfully,

P. J. Cammidge.

Nottingham-place, Marylebone, W., June 26th, 1923.

ETHYL CHLORIDE AS AN ANÆSTHETIC FOR MINOR OPERATIONS IN CHILDREN.

To the Editor of The Lancet.

Sir,—All anæsthetists will read with interest Mr. S. F. Rose's article on this subject in The Lancet of June 23rd. They will doubtless agree with all he says as to the anæsthetic virtues of ethyl chloride, but those who know how to administer it by the "open method" will certainly disagree with his dictum that "breathing with admixture of air is obsolete and unsatisfactory." Indeed, to many it will seem less enlightened to deprive a patient, particularly a child patient, of free oxygen and to enforce breathing to-and-fro into a closed bag, than to administer an anæsthetic with a free and unlimited supply of fresh air. Surely, this method must be safer than that in which all air is excluded, and the mind of the modern hygienist must revolt at the idea of a patient inhaling "the residue left from a previous administration." Mr. Rose acknowledges that children are not good subjects for nitrous oxide. Is not this because they bear deprivation of oxygen badly, and because, in them, this gas without oxygen quickly produces asphyxiation? Why, then, does Mr. Rose think that children will take ethyl chloride better without air than with it? Would he argue that fresh air is bad for children?

Mr. Rose confesses that the closed method has "one drawback"—viz., that "it may cause struggling and holding of the breath," and he mentions the "natural alarm" of the *patient* excited by its odour. He states that *both* the anæsthetist's hands are required to hold the *face-piece* in position—no wonder the little patient is alarmed! Contrast this with the open method, in which only a wire mask covered with domette is lightly applied, with one hand, at an angle with the bridge of the patient's nose, at first somewhat away from his *mouth*: and contrast the sudden presentation of the pungent vapour in a closed bag, with the gradual dropping of the ethyl chloride upon the mask, so that its vapour when inhaled is neither too pungent nor unpleasant. Mr. Rose also confesses to having experienced difficulties owing to—"holding the breath, laryngeal spasm, syncopal attacks, obstructed breathing, and vomiting." All these difficulties I submit are directly due to the closed method of administration, which enforces concentration of the vapour and causes holding of the breath and laryngeal spasm: while syncopal attacks and vomiting are in direct proportion to the duration of the rebreathing. The risks of overdose are great, and syncopal attacks and cessation of breathing are signs of overdose. Mr. Rose advocates abolition of the ocular reflexes, but in my view this is courting disaster, for when the corneal reflex is abolished the coughing reflex is also abolished; thus the sentinel of the larynx is put out of action and the risk is incurred of the patient being drowned in his own blood, or of his lungs being invaded by other foreign matter. I know some throat specialists who will not begin an operation for removal of tonsils and adenoids unless the patient's coughing reflex be brisk.

With the open method, on the other hand, I have not experienced these difficulties, except vomiting, and this rarely, in properly prepared cases, unless too deep an anæsthesia has been induced, or the induction of anæsthesia has been unduly delayed. For these reasons, some years ago, I abandoned the closed method in favour of the open method, and I teach my students at the hospital that the closed method should never be used when the open method is available, because it is more dangerous, *and because* it is wrong to risk unnecessarily a patient's life, for so trivial an operation as the extraction of a tooth.

I am, Sir, yours faithfully,

Harvey Hilliard.

Senior Anæsthetist and Lecturer on Anæsthetics
June 26th, 1923. at the Royal Dental Hospital.

FIBROMA OF THE OVARY.

To the Editor of The Lancet.

Sir,—Dr. A. W. Owen and Dr. H. A. Lediard have discussed a type of tumour in which I still take a great deal of interest. One matter of clinical as well as pathological importance is the presence or absence of ascites as a complication. I noted, when I had the opportunity of examining a very large number of solid tumours of the ovary and uterus in the surgical wards of the Samaritan Free Hospital, that peritoneal effusion by no means necessarily means malignancy. It is seen where the tumour has a perfectly smooth surface, and may be absent where there are plenty of outgrowths or inflammatory patches. Is it not, perhaps, due to lymphatic obstruction?

I am, Sir, yours faithfully,

Alban Doran,

Consulting Surgeon, Samaritan Free Hospital.
Palace Mansions, West Kensington, July 2nd, 1923.

ANCIENT SPANISH PHARMACY JARS.

To the Editor of The Lancet.

Sir,—The very fine collection of Hispano-Moresque Pottery, made by my brother, Francis W. Mark, is to be sold at Christie's on July 10th. It contains some rare pharmacy jars of the fifteenth century. I cannot help thinking that some of them would be a very valuable addition to any of the medical museums in England, and hope some generous buyer may, perhaps, help to keep them in this country. Some of them were exhibited at a social evening at the Royal Society of Medicine this time last year, and you were good enough to note the fact in The Lancet. An illustrated catalogue will be sent to you by Messrs. Amor who manage the sale. My brother is grieved that the collection should now be dispersed by auction, as his ambition was that it should be acquired for the nation.—I am, Sir, yours faithfully,

Leonard Mark.

49, Oxford-terrace, Hyde Park, W., June 28th, 1923.

*** This is a remarkable collection of pharmacy jars, and we agree with Dr. Mark that it ought to be kept intact and in some suitable centre for inspection. We hope that a purchaser with the needful public spirit will present himself on July 10th.—Ed. L.

Correspondence.

"Audi alteram partem."

A NEW WORD FOR "DEFATTED" VACCINES.

To the Editor of THE LANCET.

SIR,—In my paper [1] published in the last number of the *British Journal of Experimental Pathology* I gave an account of a method of preparing antigens from *B. tuberculosis* and some other Gram-positive bacteria, and I provisionally described the bacterial antigen so prepared as "defatted," a word that had been used conversationally in my laboratory. I pointed out at the same time that by the term "defatted" it was by no means intended to imply that all fatty or lipoidal substances present in the micro-organisms so treated had been removed. Only some of the lipoidal substances are taken away in this mode of preparation by washing with acetone after formalin treatment. It is plainly desirable, however, that the term "defatted" should not come into general use. It is as false, I am afraid, to the laws of language as it is to the experimental facts. I propose to introduce a new word to describe the vaccines or antigens prepared by this or similar methods of extraction. The essential factors in the process are the fixation treatment by formalin and the successful acetone extraction which the fixation permits. The bacteria so treated become, as I have described, non-acid-fast and Gram-negative, and are changed in appearance. They have been thoroughly washed out, and I propose to call them "diaplytes" from the Greek word *πλυτός*, washed, in its intensive form *διαπλύτος*, washed through and through. I propose to speak of "diaplyte vaccines" or "diaplyte antigens," and in the process of their preparation I should describe the acetone used as being the "diaplytic agent." I think there is justification for introducing a new word for the description of these vaccines, and it seems desirable to use one which has no previous connotations in pathology.

I am, Sir, yours faithfully,
GEORGES DREYER.

Department of Pathology, University of Oxford,
July 3rd, 1923.

THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX AND CHICKEN-POX.

To the Editor of THE LANCET.

SIR,—The main interest of the "Mild Small-pox" discussed by Dr. J. H. Garrett in his article in THE LANCET of June 23rd is its differential diagnosis from chicken-pox; and the special relevance of that lies in the financial and communal results that flow from its correct apprehension and exposition. It comes to this. If a given case be chicken-pox it costs someone, say, one guinea. If it be small-pox, it costs someone else, say, £200. A single case, to which the writer was called, was afterwards calculated to have cost almost exactly that sum. Another single case was calculated to have cost £500. The fact is this. The freedom, which many elect to enjoy, of being able to take an attack of small-pox whenever exposed to it, is a most expensive luxury to all concerned. That is the heart of the matter.

As the present unvaccinated condition of the community throws on all of us who are qualified to practise medicine the onus, whether we like it or not, of being assistants in the matter of endeavouring to keep down this portentous communal expenditure, just so it behoves us all to be equipped with a knowledge of the fundamentals of the differential diagnosis of small-pox and chicken-pox. I have laboured in season and out of season to pass this knowledge on to my colleagues ever since the late Dr. T. F. Ricketts first impressed it on me in 1897, when he went for his summer holidays that year and left me in charge of the diagnosis of London's small-pox. The differential diagnosis, of course, in a close case, turns on the due observance of many points. But the upper extremities usually afford the strongest single item of evidence. They should be exposed to the shoulder; placed in a good light; and then *read.* Not another movement nor a word is usually necessary. The writing is usually all there, to be read by those who know the key. Centrifugal is small-pox; centripetal is chicken-pox. For those who are less expert and desire to use every possible care in arriving at a diagnosis, there may be repeated the advice given in my book "How to Diagnose Small-pox" (edition 1913, page 35).

"Make a practice of plotting out the rash on a diagram of the figure. This most useful practice is strongly recommended. Incidentally it is evidence of care having been exercised, and is useful subsequently if a question is raised about the correctness of the diagnosis.

"The act of dotting in the rash compels close observation of its distribution, and often of itself leads to a correct solution. We shall see presently that a diagnosis of small-pox can sometimes be made, after all the scabs have gone, by noting the situations of the scars or stains which have been left on the skin by the rash. Make a diagram, therefore, no matter how rough, of any case that is not perfectly straightforward. You will be surprised how much it may help you. It may by itself clear up a case that has puzzled you very much."

This advice has been followed by myself in hundreds of the cases which have been referred to me for final adjudication in London and elsewhere during the last 20 years, and its value has been attested over and over again by numerous colleagues and assistants.

I am, Sir, yours faithfully,
W. McCONNEL WANKLYN, B.A. Camb.,
London, June 30th. M.R.C.S. Eng., D.P.H.

IS DIABETES MELLITUS A PROGRESSIVE DISEASE?

To the Editor of THE LANCET.

SIR,—A categorical answer to this question might be possible if the symptom-complex generally known by the name diabetes mellitus were a definite pathological entity, invariably arising from the same cause and always running a similar course, but this is by no means the case, and it therefore does not permit of a plain "yea" or "nay," any more than a similar question regarding a rise of temperature or the existence of painful sensations would do. Glycosuria with hyperglycæmia may arise in at least a dozen different ways, and with each the effects of treatment, and even the progress of the lesion in the untreated condition, varies so widely that it is impossible to lay down any general principle as to the progress of the resulting metabolic defects. As Dr. Langdon Brown has pointed out, all observers interested in the subject "must be familiar with cases which have become apparently stationary as a result of treatment by alimentary rest"; on the other hand, cases in which alimentary rest, however carefully carried out, has not sufficed to stay the progress of the condition must be equally familiar; and the same is true of insulin, for although a certain degree of immediate improvement can usually be obtained, permanent recovery of tolerance after a course of injections is by no means invariable. The reason undoubtedly is that we are not dealing with a pathological entity which always responds in the same way to similar treatment, but with a protean condition which no one form of treatment is able to control.

At the present time it is fashionable to assume that diabetes mellitus is invariably due to disease of the pancreas, disturbances of carbohydrate metabolism arising from other causes being referred to simply as glycosurias. In the absence of some reliable means for distinguishing pancreatic from non-pancreatic cases during life such a classification is merely juggling with words, but fortunately the means are now available, and by appropriate analyses of the blood, urine, and fæces it is possible to determine whether there is deficiency of the internal or external secretion of the pancreas in any case of diabetes, and also to recognise, or exclude, most of the other causes known to give rise to hyperglycæmia. Even if we limit the term diabetes mellitus to those instances in which disease of the pancreas can be shown to exist in this way however, we are still far from being able to answer the question in point with precision, although we are nearer doing so, for it would seem that the progress of the disease can be stayed, and permanent improvement be brought about, either by alimentary rest or insulin, when the hyperglycæmia is dependent entirely, or largely, upon a functional deficiency of the internal secretion of the pancreas, also that its progress, under suitable dietary restrictions, is slow when the condition arises as a result of sclerosis of the gland so that the state of the patient is analogous to that of a partly de-pancreatised dog, but that when the deficiency is brought about by an attempt to control, and compensate for, some other cause interfering with carbohydrate metabolism no treatment directed toward the pancreatic factor alone is of more than temporary benefit.

---

[1] Some New Principles in Bacterial Immunity, their Experimental Foundation, and their Application to the Treatment of Refractory Infections, Brit. J. Exper. Pathol., 1923, iv., 146.

The only answer, therefore, which can at present be given to the question under discussion in my opinion, is that, since diabetes mellitus is not a disease but a symptom-complex arising from a variety of causes, each case is more or less a law unto itself, and whether it will progress or not depends upon the accuracy with which it is diagnosed and how far suitable methods of treatment are applied to the particular conditions discovered.

ETHYL CHLORIDE AS AN ANÆSTHETIC FOR MINOR OPERATIONS IN CHILDREN.

To the Editor of THE LANCET.

SIR,—All anæsthetists will read with interest Mr. S. F. Rose's article on this subject in THE LANCET of June 23rd. They will doubtless agree with all he says as to the anæsthetic virtues of ethyl chloride, but those who know how to administer it by the "open method" will certainly disagree with his dictum that "breathing with admixture of air is obsolete and unsatisfactory." Indeed, to many it will seem less enlightened to deprive a patient, particularly a child patient, of free oxygen and to enforce breathing to-and-fro into a closed bag, than to administer an anæsthetic with a free and unlimited supply of fresh air. Surely, this method must be safer than that *in which all* air is excluded, and the mind of the modern hygienist must revolt at the idea of a patient inhaling "the residue left from a previous administration." Mr. Rose acknowledges that children are not good subjects for nitrous oxide. Is not this because they bear deprivation of oxygen badly, and because, in them, this gas without oxygen quickly produces asphyxiation? Why, then, does Mr. Rose think that children will take ethyl chloride better without air than with it? Would he argue that fresh air is bad for children?

Mr. Rose confesses that the closed method has "one drawback"—viz., that "it may cause struggling and holding of the breath," and he mentions the "natural alarm" of the patient excited by its odour. He states that *both* the anæsthetist's hands are required to hold the face-piece in position—no wonder the little patient is alarmed! Contrast this with the open method, in which only a wire mask covered with domette is lightly applied, with one hand, at an angle with the bridge of the patient's nose, at first somewhat away from his mouth; and contrast the sudden presentation of the pungent vapour in a closed bag, with the gradual dropping of the ethyl chloride upon the mask, so that its vapour when inhaled is neither too pungent nor unpleasant. Mr. Rose also confesses to having experienced difficulties owing to—"holding the breath, laryngeal spasm, syncopal attacks, obstructed breathing, and vomiting." All these difficulties I submit are directly due to the closed method of administration, which enforces concentration of the vapour and causes holding of the breath and laryngeal spasm: while syncopal attacks and vomiting are in direct proportion to the duration of the rebreathing. The risks of overdose are great, and syncopal attacks and cessation of breathing are signs of overdose. Mr. Rose advocates abolition of the ocular reflexes, but in my view this is courting disaster, for when the corneal reflex is abolished the coughing reflex is also abolished; thus the sentinel of the larynx is put out of action and the risk is incurred of the patient being drowned in his own blood, or of his lungs being invaded by other foreign matter. I know some throat specialists who will not begin an operation for removal of tonsils and adenoids unless the patient's coughing reflex be brisk.

With the open method, on the other hand, I have not experienced these difficulties, except vomiting, and this rarely, in properly prepared cases, unless too deep an anæsthesia has been induced, or the induction of anæsthesia has been unduly delayed. For these reasons, some years ago, I abandoned the closed method in favour of the open method, and I teach my students at the hospital that the closed method should never be used when the open method is available, because it is more dangerous, and because it is wrong to risk unnecessarily a patient's life, for so trivial an operation as the extraction of a tooth.

I am, Sir, yours faithfully,
HARVEY HILLIARD,
Senior Anæsthetist and Lecturer on Anæsthetics at the Royal Dental Hospital.

ANCIENT SPANISH PHARMACY JARS.

To the Editor of THE LANCET.

SIR,—The very fine collection of Hispano-Moresque Pottery, made by my brother, Francis W. Mark, is to be sold at Christie's on July 10th. It contains some rare pharmacy jars of the fifteenth century. I cannot help thinking that some of them would be a very valuable addition to any of the medical museums in England, and hope some generous buyer may, perhaps, help to keep them in this country. Some of them were exhibited at a social evening at the Royal Society of Medicine this time last year, and you were good enough to note the fact in THE LANCET. An illustrated catalogue will be sent to you by Messrs. Amor who manage the sale. My brother is grieved that the collection should now be dispersed by auction, as his ambition was that it should be acquired for the nation.—I am, Sir, yours faithfully,

LEONARD MARK.
49, Oxford-terrace, Hyde Park, W., June 28th, 1923.

⁂ This is a remarkable collection of pharmacy jars, and we agree with Dr. Mark that it ought to be kept intact and in some suitable centre for inspection. We hope that a purchaser with the needful public spirit will present himself on July 10th.—ED. L.

THE PROPHYLACTIC TREATMENT OF PUERPERAL SEPSIS.

To the Editor of THE LANCET.

SIR,—That chloroform is the commonest cause of post-partum hæmorrhage I have long recognised, and in consequence whenever I have had to use it preliminary to using the forceps, I have prepared for such result by administering a drachm of ext. ergot liq. In my opinion the commonest cause of puerperal sepsis is gonorrhœa of a chronic variety, the secondary organisms, being the fons et origo mali, preventing the healing up of tears of vagina or perineum even when carefully sutured, even when puerperal fever be not produced, and the use of an organic preparation of silver has prevented the onset of ophthalmia neonatorum. I well remember being called to a primagravida who was suffering from false pains, and discovered chronic gonorrhœa to be present. I had ten days in which to get her disinfected, but by means of plugs saturated with acid. carbol. and glycerine 1 in 20 I achieved success, and although forceps were used and the perineum torn and sutured, her temperature never rose above 98° F., and the tear healed perfectly.—I am, Sir, yours faithfully,

Blackpool, July 1st. FR. S. PITT-TAYLOR, M.B., Ch.B.

EXPERIENCES WITH ETHANESAL.

To the Editor of THE LANCET.

SIR,—I have used ethanesal for nearly 2000 cases in eight hospitals, as well as in private practice, and I should now like to state that whatever its chemical composition, ethanesal has proved in my hands to be an anæsthetic capable of producing unconsciousness with relaxation, without pulmonary sequelæ, and in most cases with an absence of post-anæsthetic vomiting. My list includes abdominal, orthopædic, throat, cerebral and cerebellar operations, and I believe the conclusion of operators and nurses coincides with mine—namely, that ethanesal gives better results than ordinary anæsthetic ether. From my notes I find that slight sickness occurs in about 15 per cent. of the cases, severe sickness in not more than about 1 per cent. At two hospitals—the West End Hospital for Nervous Diseases and the Hospital for Epilepsy and Paralysis, Maida Vale—sickness was always absent, though many of the operations lasted two or three hours.

I am, Sir, yours faithfully,

CHARLES T. W. HIRSCH.

Hyde Park Gate, S.W., June 24th, 1923.

Obituary.

SIR JAMES REID, BT., G.C.V.O., K.C.B., M.D., C.M. ABERD., LL.D. ABERD. AND GLASG., M.D. R.U.I. (HON. CAUSÂ), F.R.C.P. LOND.,

PHYSICIAN-IN-ORDINARY TO THE LATE QUEEN VICTORIA, TO THE LATE KING EDWARD, AND TO KING GEORGE.

Sir James Reid, who died on June 28th at the age of 73, was a trusted royal physician through three generations and a distinguished member of the medical profession.

Born on Oct. 23rd, 1849, he was the eldest son of the late Dr. James Reid of Ellon, Aberdeen, and was a descendant of old Scottish stock on both his father's and mother's side. His early education was received at the Aberdeen Grammar School, where he distinguished himself by being dux and gold medallist in 1865. From here he went to the University of Aberdeen, and graduated M.A. in 1869 with honours and the gold medal, and in 1872 M.B., C.M., with highest honours, while three years later he proceeded to the M.D. degree. Shortly after graduating in medicine and surgery he came to London, where he entered on practice in Upper Westbourne-terrace for two years, and spent another two years in Vienna. Returning to this country he joined his father in practice at Ellon, where he remained till he was appointed resident medical attendant to Queen Victoria on the death of Dr. William Marshall in 1881. At Windsor Castle he acted in conjunction with Sir William Jenner, and in consequence of the failing health of that physician-in-ordinary to Her Majesty, Dr. Reid was formally appointed in 1889 to the position and received in the same year the C.B. In 1895, three years after being elected a Fellow of the Royal College of Physicians of London, he was promoted to K.C.B., and on the occasion of the Queen's Diamond Jubilee was made a baronet. On the accession of King Edward, Sir James Reid was appointed physician-in-ordinary to His Majesty and subsequently to the present sovereign. Sir James Reid's services to Queen Victoria were unremitting, paying two official visits daily wherever the court might be located, while in later years those visits were even more constant. He was a frequent visitor to foreign countries with King Edward, who as a mark of special favour granted him an honourable augmentation to his arms—namely, one of the lions of the Royal Arms of England, the Royal Stags, supporting the coat, wearing round their necks a chain carrying an escutcheon charged with the Royal Crown.

Sir James Reid, who was promoted G.C.V.O. in 1901, was an honorary LL.D. of Aberdeen and Glasgow, M.D. hon. causâ of the Royal University of Ireland, and an hon. F.R.C.P. Ireland, and his various appointments included those of consulting physician to the Convalescent Home for Officers at Osborne, to King Edward VII. Sanatorium at Midhurst, to the Prince of Wales's General Hospital at Tottenham, and to the Royal Ear Hospital. He was a retired Surgeon Lieut.-Colonel in the 2nd Battalion of the Gordon Highlanders and a justice of the peace for Aberdeenshire.

He married in 1899 the Hon. Susan Baring, daughter of Lord Revelstoke and then maid of honour to Queen Victoria, and leaves two sons and two daughters.

JOHN GIRVIN, M.R.C.S. ENG.,

COLONEL, A.M.S. (RETIRED).

LAST week there died in the person of John Girvin a loyal public servant, an educated practitioner, and an able administrator. Born in 1861 he entered St. Bartholomew's Hospital as a student in 1882, after an "apprenticeship" at Dorking—an unusual occurrence even in the "eighties," and qualified M.R.C.S., L.R.C.P. in 1886, receiving his first commission in the Army Medical Service in July of that year. From Colchester he proceeded to India, where he remained for six years, afterwards serving in Ireland, Egypt, and Cyprus. Later he was appointed to the medical charge of the Guards in Wellington Barracks, and for over two years was secretary to Sir Arthur Sloggett. He was subsequently sent to Sierra Leone and then to India a second time as senior medical officer at Hyderabad, Scinde. He returned home in 1913, and during the war helped to form a new hospital for Gallipoli, being appointed, firstly, as chief-in-charge of the advanced base hospital, and secondly, as Deputy Director of Medical Services, a position he held until the evacuation of the troops. After Gallipoli he again served in Egypt, where he was in charge of the 27th General Hospital. On returning to England after the war he fell into ill-health, caused in part by the stress of military service and in part also by the loss of his only son, and he retired with the rank of full colonel at the end of 1918. By temperament Colonel Girvin was silent and reserved, and when selected to serve in a sphere of action where ceremony and ritual are essential observances, his love of order, method, and precision caused him to respect formality and to appreciate the marks of dignity and responsibility. No one, testifies one of his colleagues, could be more faithful to his corps nor more meticulous in regard to the honour of the medical service than was John Girvin.

EDWARD LIDDON, M.D. Edin., M.R.C.S., L.S.A.

Dr. Edward Liddon, who died at Taunton on June 26th at the age of 92 years, was one of the best known practitioners in West Somerset during the second half of the nineteenth century. The son of Captain Matthew Liddon, R.N., he received his medical education at King's College, London, becoming M.R.C.S. in 1852 and L.S.A. in the following year. Proceeding to Edinburgh he graduated M.D. in 1854, taking the gold medal for his thesis. He also studied in Paris and later became a Medical Associate of King's College. After holding appointments at Bath Hospital and at the Consumption Hospital, Brompton, he joined an uncle in practice at Taunton in 1855, and carried on a large general and consulting practice until he retired in 1902. At the Taunton and Somerset Hospital, in which he always maintained a generous interest, he held the post of hon. physician for many years, becoming later a consulting physician and finally president. His lifelong aim was the improvement of the status and education of nurses; he was largely responsible for the foundation of the Nursing Institute attached to the Taunton Hospital, and was a pioneer in the work of providing village nurses to attend the poor. Dr. Liddon had many interests outside his profession: he was a J.P. for Somerset and a leading Churchman and educationist, being prominent in the establishment of the Huish School, now one of the most successful secondary schools in Somerset. An enthusiastic volunteer, Dr. Liddon retired with the rank of Surgeon Lieut.-Colonel of the 2nd Vol. Batt. of the Somersets. Hunting was his recreation; he was well known with the local packs of staghounds and foxhounds and was master for many years of the Taunton Vale Harriers. A man of strong personality, he held decided opinions, but was not carried away by prejudice. He was very widely respected by medical colleagues and public alike, and his benefactions among his poorer patients were many but not generally known. Dr. Liddon was twice married and leaves a widow and two sons.

Medical News.

University of Oxford.—At recent examinations the following candidates were successful:—

Examination for Degree of M.Ch.

Charles H. Carlton, St. John's.

Final Examination for Degree of B.M.

Materia Medica and Pharmacology.—George R. P. Aldred-Brown, Keble; Eric N. Allott, Balliol; Leslie J. Barford, Queen's; Louis W. H. Bertie, St. John's; Robert B. Bourdillon, University; Vernon H. Brink, Hertford; Clarence S. Broadbent and Thomas A. J. M. Dodd, Queen's; Leslie O. F. Fysh, St. John's; Samuel Harris, Jesus; Thomas B. Hodgson, Queen's; Alfred Kendrew, Christ Church; Raymond Lewthwaite, Magdalen; Philip Morton, Keble; Eric L. Newell, Jesus; William D. B. Read, Magdalen; Thomas E. Ryves, Trinity; Bernard G. Scholefield, Christ Church; Richard W. A. Simmons, Oriel; Robert A. Walsh, Magdalen; Arthur Q. Wells, St. John's; Evelyn C. Whitehall-Cooke, Queen's; David O. Williams, Jesus; and Rosa S. Wordsworth, Lady Margaret.

Pathology.—Murray McCheyne Baird, New; Richard E. D. Cargill, Christ Church; Cyril W. Carter and Thomas A. J. M. Dodd, Queen's; Cyril L. Elgood, Balliol; Kenneth J. Franklin, Hertford; Douglas R. Gawler, University; Cyril A. H. Green, Trinity; Harold E. Harding, Oriel; John R. B. Hern, New; John A. Macfadyen, Brasenose; Victor P. Robinson, St. John's; James P. Shaw, Balliol; Insall M. Sidley, Christ Church; Harold N. Stokoe, Pembroke; John G. S. Thomas, Hertford; Bertram E. Tompson, Brasenose; George P. Wright, Exeter; and Mathilde E. F. Bugnion and Janet M. Vaughan, Somerville.

Forensic Medicine and Public Health.—Owen D. Ballinger, University; David T. Barnes, St. John's; Edward F. Chapman, Magdalen; Alexander M. Cooke, Jesus; Richard S. Creed, Magdalen; Robert van Buren Emmons, New; John A. Macfadyen, Brasenose; George F. L. Mitcheson, Christ Church; Eric B. Strauss, New; Tom S. Townsend, Jesus; Horace F. Turney, Magdalen; and Cicely D. Williams, Somerville.

Medicine, Surgery, Midwifery.—John W. Alden, non-collegiate; Philip W. Boobbyer, Keble; Thomas A. Brown, Exeter; Alexander D. Dyson, Corpus Christi; Robert van Buren Emmons, New; Reginald V. Facey, Brasenose; Humphrey C. Hill, Hertford; James P. Shaw, Balliol; Arthur L. B. Stevens, Christ Church; Eric H. Watkins, Hertford; Arthur Q. Wells, St. John's; Claude R. Young, University; William A. Young, Jesus; Sibyl R. Eastwood, Society of Oxford Home-Students; and Cicely D. Williams, Somerville.

University of Sheffield.—At examinations held recently the following candidates were successful:—

M.D. Examination: Robert Platt.

Final M.B., Ch.B. Examination.

Oswald H. Billington, Reginald L. Brown, Alice C. Caiger, Ida Coates, Henry Cretney, Andrew S. Drummond, Clifford S. Dunbar, Denton Guest (with 2nd class honours), William H. Harding, Mona E. Hatherley, Albert B. Nutt, Muriel R. Powell, James E. Schofield, and Annie D. Sykes.

Third M.B., Ch.B. Examination.

William F. L. Castle, George S. Davidson, Edward M. Dearn, Alys M. Gregory, Sidney G. Meanley, and Oscar H. Silverman.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—L. P. Garrod, St. Bart.'s Hosp.; B. Hart, Sheffield; L. K. Ities (Sect. II.), London Hosp.; and M. S. Mahmud (Sect. II.) and B. Teverson, St. Mary's Hospital.

Medicine.—L. P. Garrod, St. Bart.'s Hosp.; E. W. Hicks, St. Thomas's Hosp.; and B. Teverson, St. Mary's Hosp.

Forensic Medicine.—L. P. Garrod, St. Bart.'s Hosp.; E. W. Hicks, St. Thomas's Hosp.; J. A. H. Sykes, Edinburgh; B. Teverson, St. Mary's Hosp.; and H. Whitby, London Hosp.

Midwifery.—D. Dimitrijevitch, Oxford and St. Mary's Hosp.; L. P. Garrod, St. Bart.'s Hosp.; L. Statnigrosh, Middlesex Hosp.; and B. Teverson, St. Mary's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: L. P. Garrod, B. Hart, E. W. Hicks, and B. Teverson.

Royal Institute of Public Health.—The Congress in 1924 will be held in Bordeaux from June 4th to 9th inclusive. The President will be Lord Burnham, and the local hon. secretaries Dr. Rene Cruchet, Professor of Medicine in the University of Bordeaux, and Mr. G. Faure, treasurer of the Chamber of Commerce, Bordeaux. The meetings will take place in the University. Special arrangements are being made for travelling and hotel accommodation.

Epsom College.—The seventieth annual general meeting of the Governors of Epsom College was held on June 29th at 49, Bedford-square, London, W.C., Sir Henry Morris, treasurer, presiding. The scrutineers reported that the successful candidates for pensionerships and foundation scholarships were: Ordinary Pensionership, Adelaide Lynch; Foundation Scholarships: Thomas M. Newton, Jeffrey O. Timms, James D. Johnston, Irwin J. McGhie, Denis A. Sanford, H. Vincent Adcock. In submitting the annual report of the Council Sir Henry Morris drew attention to the loss which the College had sustained by the death of Mr. Clement Locke Smiles, and by the retirement from the Council of Mr. Walter Archibald Propert, the grandson of the founder of the College, and announced that Mr. W. Douglas Crossley, who entered the College as a Master in September, 1888, and was appointed bursar in September, 1890, was about to retire, after having served the College for practically 35 years. He further reported that Mr. Bluett, one of the honorary auditors, had died since the last annual general meeting, and that the Council proposed that Colonel Norman C. King, the Registrar of the General Medical Council, should be appointed an honorary auditor in his place. Continuing, Sir Henry Morris referred to two pension funds recently instituted, and mentioned that the Council had decided to propose that, in consequence of the increased cost of living, amendments in the by-laws should be made with the view of permitting a somewhat larger income than that hitherto held by persons wishing to become candidates for various pensionerships—namely, £100 a year instead of £60. He stated that steps had been taken to begin at once the work of rebuilding the nave of the chapel in harmony with the new chancel, in spite of the fact that the funds in hand were not sufficient for the purpose, and he urged all friends of the College to do their best to secure contributions for this purpose. In thanking those persons and organisations that had assisted the Royal Medical Foundation attached to the College by obtaining donations and subscriptions during the year, he stated that it had long been customary to elect as vice-presidents those who had collected the sum of £1000, and as the Rev. Walter J. Barton, the late headmaster, had completed this sum, the Council proposed that he should be elected a vice-president of the College. At the termination of the proceedings a cordial vote of thanks to the chairman was proposed by Dr. Raymond Crawfurd, seconded by Mr. Hollis Walker, K.C., and carried with acclamation.

SOCIETY FOR THE STUDY OF INEBRIETY.—The next meeting of the society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on July 10th, at 4 P.M. Prof. A. Louise McIlroy will open a discussion on the Influence of Alcohol and Alcoholism upon Antenatal and Infant Life.

CALEDONIAN MEDICAL SOCIETY.—The thirty-eighth annual meeting of this society was held on June 29th in the rooms of the Aberdeen Medico-Chirurgical Society. Dr. David Rorie took as the subject of his presidential address the Career of Dr. George Boswell, who was surgeon to King James VI. of Scotland. The meeting was largely attended, and at the dinner the same evening 70 members and friends were present. It was arranged to hold the next meeting of the society in Liverpool under the presidency of Dr. David Smart.

COMPLIMENTARY DINNER TO DR. WILLIAM MAYO.—The Surgical Section of the Royal Society of Medicine gave a complimentary dinner to Dr. William Mayo, of Rochester (Minnesota), at the Hotel Cecil on June 27th. Mr. James Berry, the President of the section, was in the chair, and there was a large attendance of Fellows and Members of the section from all parts of the United Kingdom. After the loyal toasts, the chairman proposed "Dr. William Mayo," giving a vivid account from first-hand information of the Mayo Institute at Rochester, and some pleasing glimpses into the lives of the Brothers Mayo. Dr. Mayo, in responding, spoke of the zeal for education in a State of 3 million inhabitants which had 11,000 students attending its University and 8000 more intimately connected with it. The accumulated income of the Mayo Clinic, amounting to 7 millions, not including real estate of 3½ millions, had now been handed over as permanent endowment to trustees who understood what surgical treatment meant, and he hoped that the Clinic was thus safe for a generation. Sir Berkeley Moynihan proposed "American Surgery," reciting the names and achievement of a series of American surgeons, most of whom bore Irish names, amongst them Dr. William Mayo, who, he said, was "the greatest statesman in surgery of all time." Among the characteristics of American surgery he included masterly technique, fertility in suggestion, integrity of utterance, and an unbounding hospitality to new ideas. Dr. Donald Balfour, who responded, sketched the problem of surgery in American rural practice and the possibility of raising the general standard of surgery in the U.S.A.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—At a meeting of the General Council, held on June 26th, at 1, Wimpole-street, W., with Sir George Makins in the chair, the Council nominated the honorary officers of the Association for election at the annual meeting. The President, Sir George Makins, having intimated his desire to retire from office, it was unanimously agreed on the proposal of Mr. Carson, seconded by Dr. Myers, that Sir Arbuthnot Lane be nominated to serve in his place. It was proposed from the chair and unanimously agreed that, if willing, Sir Humphry Rolleston be nominated for re-election as chairman of the Executive Committee. On the proposal of Dr. C. B. Heald, seconded by Dr. C. O. Hawthorne, it was agreed to make no further nominations for the office of honorary treasurer, and Sir John MacAlister was unanimously nominated for re-election and also Mr. H. J. Paterson and Dr. H. MacCormac as hon. secretaries. The reports of the hon. treasurers and secretaries were received and approved for submission to the annual meeting. It was agreed that the date of the annual meeting be fixed for Friday, July 13th, at 5.30 P.M.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The programme of the next quarterly meeting, to be held in London next week, is as follows: On July 10th, at 11.30 A.M., at 11, Chandos-street, a paper will be read by Dr. R. M. Stewart, entitled General Paralysis: Its Unsolved Problems. At 3 P.M., at the Royal Society of Medicine, 1, Wimpole-street, W., Lieut.-Colonel E. Goodall will give his presidential address on Considerations, Bacteriological, Toxicological and Hæmatological, and others therewith associated bearing upon the Psychoses, and at 4.30 P.M. Dr. J. G. Porter Phillips will give an address on the Early Treatment of Mental Disorder: A Critical Survey of the Out-patients' Department. On July 11th, at 10 A.M., at 11, Chandos-street, a discussion on the Relation of Chronic Sepsis to the So-called Functional Mental Disorders will be opened by Dr. Henry A. Cotton, followed by Sir W. H. Willcox, Dr. William Hunter, Dr. D. Chalmers Watson, and Dr. T. C. Graves. Dr. Clement Lovell will read a paper on the Surface Tension of the Serum in Anxiety Psychoses. In the evening the annual dinner of the Association will be held at the New Metropole Hotel, Northumberland-avenue, W.C. On July 12th, at 10 A.M., at 11, Chandos-street, a paper on the Histological Examination of 110 Cases of the Pituitary Body of Patients Dying in Asylums and Hospitals will be read by Sir Frederick Mott, F.R.S., and Dr. I. M. D. Robertson, and one on the Psychogenic Factor in the Causation of Mental Disorder by Dr. Thos. Beaton. At 3 P.M. a visit will be paid to the Maudsley Hospital, Denmark Hill, under the guidance of Dr. Edward Mapother. On July 13th, at 10 A.M., at 11, Chandos-street, the following papers will be read: Basal Metabolism in Mental Disorders, especially Dementia Præcox, and the Influence of the Diathermic Current on the Same, by Dr. James Walker; the Diagnosis of Dysenteric Infections in Mental Hospitals, by Dr. A. A. W. Petrie; and the Ranchi European Mental Hospital, India, communicated by Major Owen Berkeley-Hill.

TUBERCULOSIS CONFERENCE AT BIRMINGHAM.—The ninth annual conference of the National Association for the Prevention of Tuberculosis is to be held in the University, Edmund-street, Birmingham, from Thursday, July 12th, to Saturday, July 14th. The Lord Mayor of Birmingham will formally open the conference at 10.30 A.M. on Thursday, when a discussion will follow on the Care of Advanced Cases of Tuberculosis. The other main subjects for discussion will be the Extent and Nature of Damage Done by Tuberculosis Derived from Infected Milk; the Work of Tuberculosis Care Committees; the Relative Prevalence of Tuberculosis Among Workers in Different Trades; and the Notification of Tuberculosis with the Proposed Amendments of Procedure. The public address on Friday evening, at 7.30, will be delivered by Sir Robert Philip on the Actual Position of the Tuberculosis Problem To-Day. Saturday will be left free for tours and visits to institutions.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JULY 3RD.

The Value of Garden Suburbs.

THE Earl of ONSLOW moved the second reading of the Housing, &c. (No. 2) Bill, which has passed through the House of Commons.

Lord DAWSON of PENN said that for the cure of disease they were increasingly moving in the direction of open-air treatment. In the near future hospitals would be to a large extent constructed in the open with open wards. If they were going to use fresh air for the cure of disease, how much more profitable if they used it for its prevention. Any remedy, however, which was too ambitious would be crushed under its own weight, and any reform which did not carry educated opinion with it would defeat its own end. Therefore it appeared that this Bill went as far as in the present state of knowledge and public opinion it was wise to proceed. He urged the Government to give more generous consideration to that part of the Bill which was concerned with the housing of communities—to those provisions which enabled town planning and garden suburbs to be tried and expanded. Nothing could be more productive of permanent good than the extension of town planning and of garden suburbs. The Government ought to give as generous a trial as possible to the garden suburb schemes set forth in the second part of the Bill.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 27TH.

SCOTTISH HEALTH ADMINISTRATION.

THE House went into Committee of Supply on a Vote of £1,773,730 for the salaries and expenses of the Scottish Board of Health, Captain FITZROY in the chair.

Captain ELLIOT (Parliamentary Under Secretary for Health for Scotland) said that his department had provided three main lines of statistics which it seemed to him would be of great value in estimating the effect of the recent trade depression on the health of the population. In Scotland in the years 1910–14 the average death-rate from tuberculosis was 172 per 100,000; in 1918 the rate was 118; in 1922, 119. They were therefore very considerably better than they were in the years before the war. In the years 1910–14 the five years' average for England and Wales was 140; in 1921, 113; in 1922, 112. As to phthisis, in Scotland the average death-rate for 1910–14 was 111, while in England and Wales it was 102. In 1921 the Scottish rate for phthisis was 81, while it was 88 in England and Wales. In 1922 the Scottish rate was 83, while in England and Wales it had gone up to 89. These were index figures, but they were most valuable at arriving at the true state of affairs. He would give the Committee the 1918 death-rates for some other countries. In that year the death-rate from tuberculosis (all forms) was in Scotland 160, and in England and

Wales 169. In Budapest it was 611; Warsaw, 591; Lodz, 775; Jugo-Slavia, 400 to 500; and Czecho-Slovakia, that was Prague, 386. The death-rate from influenza in all forms in our country for the three waves that swept over the country was 477 per 100,000, so that in the foreign countries he had quoted the death-rate was in relation to tuberculosis greater than the death-rate in this country from influenza.

The average infantile mortality-rate per 1000 births for 1871–80 was in Scotland 123 and in England and Wales 149. That was before the grants in regard to child welfare were made. The figures for 1911–15 were 113 in Scotland and 149 in England and Wales. In 1920–21–22 the figures for Scotland were respectively 92, 90, and 101, while for England and Wales they were 80, 83, and 77. In the first quarter of last year the rate was 141. That was when maternity and child welfare grants were given, while for the corresponding quarter of this year the figure was 98. As to insurance and sickness benefit the expenditure per week per insured person was 2*d.* in 1913 and 2¼*d.* in 1914, and the expenditure on males on sickness benefit was less than 2¼*d.* in 1920 and less than 2¾*d.* in 1921. The increase must be balanced by the fact that a big increase in the percentage of benefit had been decreed by statute. These three lines of argument went far to substantiate the contention he had advanced as to the surprising extent to which the present system was preserving the health of the people under the great industrial depression.

Referring to the tuberculosis grant, the hon. gentleman said that, roughly speaking, the Board had been able to implement their promise to pay 50 per cent. of the grant to the local authorities. A reduction was contemplated in three cases because the figure of the local authorities in those areas was a very high one, and higher than that of other local authorities who were approximately in the same position. The estimated cost of the middle ward in Glasgow was 71*s.* per week, and there was a wide discrepancy there. The figure for Glasgow for the maintenance of tuberculous patients treated in fever hospitals was 57*s.* per week, and the corresponding Mid Lanark rate was 46*s.*, as compared with the Edinburgh figure of 37*s.*, the Dundee figure of 36*s.*, and Aberdeen 38*s.* It would therefore be seen that there was, in the Board's opinion, need for further scrutiny of these figures. The reductions suggested would still enable the Glasgow authority to pay some 40*s.* per week, which was higher than Edinburgh, Dundee, or Aberdeen. Glasgow, with 29 per cent. of beds, proposed to spend 39 per cent. of the expenditure, and in the middle ward, with 10 per cent. of beds, it was proposed to spend 15 per cent. of the expenditure. The Scottish local authorities had had one or two meetings on questions of public health, and in particular there had been a very interesting conference in connexion with venereal diseases. There was a widespread feeling that further powers of compulsion should be given to these authorities by statute, particularly in relation to children. He hoped that the report of the committee appointed to inquire into the high death-rate among mothers would shortly be presented.

Mr. Sullivan moved to reduce the Vote by £100.

Dr. Chapple said there was one very satisfactory feature of the report of the Scottish Board of Health, which was that notwithstanding the enormous unemployment and the tremendous fall in wages the death-rate was going down, the disease-rate had been going down, and mortality from tuberculosis had been going down. The unsatisfactory aspect of the report was that part in which they were told that the lack of improvement in regard to tuberculosis was largely due to the fact that they had not enough sanatoriums and not enough money. It was a tragedy that there should be people in Scotland suffering from any dire but preventable and curable disease who could not get the advantage which modern medical science and modern preventive treatment made possible for them.

In the debate which followed, Mr. Maxton, a Glasgow Labour Member, said that at a time when an epidemic was raging in Scotland, disease was at its worst, and the death-rate at its highest, hon. gentlemen on the Ministerial side of the House, in the interest of saving money, which the right hon. Baronet the Member for the City of London approved of, issued a circular condemning children to remain in the breeding ground of infection. He called it murder, and the men who initiated the policy were murderers. They had the blood of infants on their hands.

The hon. Member was called upon to withdraw, but he refused to do so, and eventually the Speaker was called in, and Mr. Maxton was suspended from the service of the House by 258 votes to 70.

The withdrawal of the hon. Member led to further trouble on the Labour benches, and before order was finally restored three other Glasgow Labour Members, Mr. Wheatley, Mr. Stephen, and Mr. Buchanan, were also suspended.

Mr. Macpherson, continuing the debate, referred to the work of the Highlands and Islands Medical Service, which he said read like a romance. One fact that had always impressed itself upon him was the heroism, gallantry, the kindness and self-sacrifice of the Highland doctor. He should be glad if it was possible where the district was remote and difficult to increase what was called the mileage of these doctors. The same praise could be meted out to the nursing staff. The State should see to it that every doctor in the Highlands had a house provided out of the funds of the Board. Referring to the outbreak of botulism, which occurred in his constituency last year, Mr. Macpherson said that nothing could have exceeded the care with which the Board undertook their investigations and the promptitude with which they were on the spot.

The motion to reduce the Vote was negatived on a division by 209 votes to 118, and the vote was then agreed to.

Typhus Fever in Skye.

Mr. Maxton asked the Under Secretary to the Scottish Board of Health what were the conditions prevailing in the Island of Raasay, Skye district, which rendered possible a recrudescence of typhus fever; and what action had been, or was proposed to be, taken to remove the predisposing cause of a recurrence of typhus fever in the island.—Captain Elliot replied: While the primary cause of the outbreak of typhus fever in this locality last year is unknown, there is no reason to believe that the epidemic resulted from causes other than those social and personal conditions of life which are usually responsible for this disease. The medical officer who was sent to deal with the outbreak experienced considerable difficulty in taking measures with a view to preventing a recurrence of the disease owing to the active opposition of a proportion of the inhabitants to the treatment considered necessary by him. The matter was referred to the local authority, who did not consider it expedient in the whole circumstances to resort to compulsory measures.

Unemployment and Sickness in Salford.

Mr. Tillett asked the Minister of Labour whether he was aware of the serious condition of the 10,000 unemployed in Salford and the ill-health arising therefrom; and what steps he proposed to take to mitigate the evil and danger of this state of affairs, which had remained practically stationary during the past six months.—Sir M. Barlow replied: I am aware of the regrettable extent and duration of the unemployment in Salford. Assistance has been given to various relief schemes in the locality, both through the Ministry of Transport and through the Unemployment Grants Committee, and, of course, any further schemes put forward would receive careful consideration. In addition, I understand that the Ministry of Transport are now in communication with the Lancashire County Council with a view of inaugurating in the district some substantial road works for the relief of unemployment.

Medical Research Grant.

Mr. Becker asked the Minister of Health how the grant of £135,000 made to the Medical Research Council was disposed of; the chief channels of its disposal; and was £5000 the only sum which was apportioned to cancer research.—Lord E. Percy replied: Roughly, one-third of the annual grant of £130,000 is allocated by the Medical Research Council to the payment of their research staff and the maintenance of their central laboratories at the National Institute for Medical Research. The remainder is distributed in grants in aid of research work carried out by universities, hospitals, and other centres throughout the country. In addition to the sum of £5000 expended in grants for work directly upon cancer, radium owned by the Government to the value of over £70,000 is made available by the Council for approved research into the treatment of cancer. I would, moreover, remind my hon. friend that the problems of cancer may be solved sooner, and perhaps only, through advances in fields of medical science other than the direct study of the disease itself, and that, accordingly, advances in the knowledge of cancer are effectively promoted by the grants for research in the more primary parts of the medical sciences. I may add that the allocation for cancer work varies from year to year, as the Council find useful opportunities for supplementing the work done by the Imperial Cancer Research Fund and other institutions devoted specially to this subject.

Panel Practitioners' Conditions.

Sir Kingsley Wood asked the Minister of Health when the discussion between himself and representatives of the insurance practitioners and approved societies was to take place; and whether he proposed to make a statement to the House on the conclusion of such discussion.—Lord E. Percy replied: The Insurance Acts Committee met representatives of the Ministry yesterday to discuss recommendations of the Panel Conference in regard to the revision of the terms of service. Further discussion will be necessary on certain points with the Insurance Consultative Council. No joint conference, such as my hon. friend suggests, is contemplated at present, and it is unlikely that any definite decision as to the rate of remuneration will be reached before the autumn.

Mr. D. G. **Somerville** asked the Minister of Health the form in which the official proposals for the renewal of the panel system under the National Health Insurance Act would come before the House; and whether any such scheme would be considered in the autumn.—Lord E. **Percy** replied: Any changes in the terms of service of insurance practitioners apart from the amount of the practitioner's remuneration will involve an amendment of the regulations, and any amending regulations will be laid before Parliament in accordance with the provisions of Section 65 of the National Insurance Act, 1911. My right hon. friend is not yet in a position to say when the amending regulations will be made.

Mental Deficiency Administration.

Mr. **Frank Gray** asked the Minister of Health whether he was aware that many complaints had been made in several localities of the exercise of the wide powers conferred by the Mental Deficiency Acts, 1913 to 1919, over individuals; and whether he would cause inquiry to be made into the exercise of these powers and the foundation for the complaints made.—Lord E. **Percy** replied: As far as I am aware, the powers referred to are exercised with care and discretion. If the hon. Member has any specific cases in mind and will give me particulars I will ask the Board of Control to investigate them.

Diagnosis of Small-pox.

Mr. **Becker** asked the Minister of Health the number of cases of small-pox notified during the first three weeks of this month; had he any information to the effect that in parts of the country small-pox had been wrongly diagnosed as chicken-pox; whether the spread of small-pox was increasing or not; and whether his department attributed this to people refusing to be vaccinated.—Lord E. **Percy** replied: The figures for the week ending June 23rd are not yet available, but the number of cases of small-pox notified during the previous three weeks was 183. This figure is subject to revision in the light of information which may subsequently be received. The answer to the second part of the question is in the affirmative. As regards the third and fourth parts, my right hon. friend is advised that there has recently been an increase in the prevalence of this disease, and that the neglect of vaccination has undoubtedly contributed to its spread.

Small-pox in Gloucester.

Mr. **Lansbury** asked the Minister of Health whether, seeing that two medical men practising in Gloucester, who had had before them many more cases than any other medical men in the town, had not notified a single case of small-pox, but had certified a large number of patients as suffering from chicken-pox, and seeing that the medical officer of the town did not agree with the diagnosis and report of the Ministry of Health officials, asserting that small-pox was prevalent in the town, he would order a public inquiry into the whole facts connected with this assumed outbreak of small-pox, the inquiry to be conducted by a committee of laymen with expert advisers.—Lord E. **Percy** replied: My right hon. friend is satisfied that small-pox is prevalent in Gloucester, and sees no reason for a public inquiry into that point.

Tuberculous Treatment in Scotland.

Mr. **Wheatley** asked the Under Secretary to the Scottish Board of Health if it was the intention of the Board of Health to reduce the grant to local authorities in Scotland towards the cost of tuberculous treatment in 1923–24; and if he has received any protest from local authorities on the subject.—Captain **Elliot** replied: The Board have informed local authorities, with three exceptions, that they will pay the usual 50 per cent. grant on the actual expenditure included in their estimates for the year 1923–24, subject to audit of claims. In the case of the three authorities referred to, certain items of their estimates made provision for expenditure at rates much in excess of those for other comparable authorities, and the Board have intimated that they will pay grant only on an amount less than that provided in the local authority's estimate. As regards expenditure not included in the estimates for the year for which approval has been asked by local authorities, and to which the Board on the merits have no objection, the Board have intimated that grant can be paid only in so far as there are savings available. With regard to the last part of the question, the Board have received a copy of a resolution adopted at a conference of representatives of local authorities to the effect that the distribution of grant in aid of the treatment of tuberculosis should be made on the basis of actual approved expenditure, and not on estimated approved expenditure. The distribution of the grant for 1923–24 will, as I have explained, be substantially on the lines recommended in this resolution.

Deaths from Cancer.

Major **Molloy** asked the Minister of Health what proportion of deaths in the four decades, 1881–90, 1891–1900, 1901–10, 1911–20, and in the year 1921 from all causes other than violence or accident were due to cancer in those who lived to be 30 or upwards.—Mr. **Neville Chamberlain** replied: From 1881–1910 deaths were grouped by age in five-year periods up to 25 years, and afterwards in ten-year periods, so that it is not possible to give the required particulars for ages from 30 and upwards. The following table gives the proportion for ages from 35 and upwards for the whole of the period covered by the question, and, in addition, the proportions for 1911 to 1920 and 1921 for ages from 30 and upwards.

Percentage of Total Deaths (excluding Violence) due to Cancer.

Age 35 Years and Over.	
1881–1890	6·6
1891–1900	8·5
1901–1910	10·9
1911–1920	12·4
1921	15·3

Age 30 Years and Over.	
1911–1920	12·3
1921	14·9

Thursday, June 28th.

Ministry of Health Vote.

The House went into Committee of Supply on a Vote of £12,504,210 for the salaries and expenses of the Ministry of Health, Mr. **James Hope** in the chair.

Mr. **Neville Chamberlain** (Minister of Health) said that ever since he had taken part in public affairs, whether local or national, he had felt that improvements in the public health were of more importance to the nation than anything else. Sickness and ill-health meant that a vast army of people had to be maintained at the cost of their fellows while they were unable to work, and the withdrawal from the productive activity of the country of a large number of people who otherwise might contribute to the nation's wealth. Taking only the insured population in the year 1922, upwards of 19,500,000 weeks of work were lost from this cause alone. It was some consolation to reflect that the work that was being done by way of preventive medicine was not in vain. During the first 10 years of this century the death-rate in this country was 15·4 per 1000. In the following 10 years, including the war years, it had fallen to 14·3, not including the deaths of those who were actually killed in the war. Last year it had fallen as low as 12·8. After quoting figures to show the decrease in infantile mortality in recent years, Mr. Chamberlain said that the expectation of life among all classes of the population was steadily increasing, and a baby born to-day could reasonably expect to live 12 years longer than its grandfather. Tuberculosis and cancer were very far from being the most fatal diseases. Easily the first in fatal effects were the respiratory diseases—pneumonia, bronchitis, &c.—the high mortality from which was due to the congested conditions and polluted atmosphere of our large towns. Next to the respiratory diseases were those of the heart, and after them came the diseases of the nervous system. Cancer, which was fourth on the list, accounted for about 96 per 1000 of all deaths from all causes. He was sorry to say that this disease was increasing among our people. In 1900 cancer deaths per million of the population were 829; in 1910 they had risen to 967, and in 1921 to 1215. Two allowances must be made. The first was that methods of diagnosis were constantly improving. Then the fact that people lived longer than formerly brought a larger proportion of the population into that comparatively short span which was called the cancer age. Cancer was most prevalent between the ages of 50 and 60. He had at the Ministry of Health a Standard Medical Committee on Cancer which advised him from time to time. Researches were being undertaken by three bodies—the Cancer Research Fund, the Middlesex Hospital, and the Cancer Hospital in the Fulham-road. In addition the subject was constantly under the attention of the Medical Research Council, and in the last few weeks another body had started, the British Empire Cancer Campaign. If that new body could succeed in coöperating with the existing bodies and in forming some sort of coördinating influence between them all he would heartily welcome its existence and be glad to give it his support.

He was glad to be able to give a much more encouraging account of tuberculosis than of cancer. In 1867 the deaths from tuberculosis per million of the population were 2653; in 1887 they had fallen to 1685. In 1907 they were only 1125, and last year they were only 885 per million. Just lately two new methods of treatment had come under the notice of the Ministry of Health—the first devised by Mr. Spahlinger and the other elaborated by Prof. Dreyer of Oxford. A little while ago venereal disease was occasioning a great deal of anxiety on account of the great increase in the number of cases after the war, and arousing a great deal of controversy in the activities of two different schools of thought as to the proper method of treatment. Fortunately the disease was fairly rapidly on the decline, and they were going back to more normal methods and figures. They might attribute a great deal of this result to the fact that they had established a number of clinics throughout the country of which there were 191 now in existence. He hoped that the number of clinics might be increased. The report of Lord Trevethin's Committee seemed at last to offer some basis upon which these two schools of thought might come together and work harmoniously in the future for the common good. He hoped that it might be possible for him to make some progress on the main lines suggested by that committee.

Small-pox, owing to the amount of vaccination that went on, was for some time almost extinct in this country. In 1917 there were only seven cases, but he was sorry that there had been a very serious revival in the prevalence of this disease. In 1922 there were upwards of 973 cases, and this year up to June 16th there had been already 955 cases. He thought it was his duty to speak plainly on this matter, and he considered that the situation was distinctly serious. Twenty years ago 75 per cent. of the children born were vaccinated, and to-day only 38 per cent. were vaccinated. There was a possibility of their being faced with an outbreak of small-pox which would not only be dangerous to health and even to life but would certainly inflict a very serious damage upon the commerce of the country. He was watching, and would continue to watch, the situation with close attention, and in the meantime he desired to emphasise as strongly as he could that the one sure protection against small-pox was vaccination, and that those who not only refused to be vaccinated themselves but gratuitously advised others to follow their example were taking upon themselves a very grave responsibility, which they might some day be called to account for at the bar of public opinion. Reverting to the question of infantile mortality, the right hon. gentleman said that he thought it might largely be taken to be the result of the infant welfare centres, of which there were now 1950 in the country. They wanted more centres, more pre-natal clinics, more free medical attendance, more health visitors, and improved practice in midwifery.

Up to the present the Voluntary Hospitals Commission had spent £425,000 out of the £500,000 voted by Parliament. Fortunately the deficits for 1921 were substantially less than had been estimated, and the deficits had now practically all been cleared off with the exception of a few cases in which the hospitals were unable to raise the equivalent amount of money to justify a grant being made. In 1922 it was believed that the deficits would prove to have been less than was anticipated. The success of what was called mass contributions had substantially increased hospital incomes. Although the ordinary expenditure might increase still further in the future, with the revival of trade and the reduction of taxation the resources of the hospitals might be expected to increase, and they need not take a gloomy or despairing view of the future. More beds were required to accommodate patients undergoing operations or some specialised treatment, and the result of the natural increase in demand, coupled with the fact that there had been no increase in the supply, had been that every hospital now had a terrible waiting list. Unless the voluntary system was able to provide for the inevitable growth in the number of beds required and to bear the increased burden of maintenance necessitated by that, the system could not be said to be standing on safe ground. While the outlook was still serious, he should consider it a mistake to come to any hasty conclusion upon it, because the voluntary system had shown such remarkable vitality and persistency in extraordinarily trying times. One other way in which some relief could be given to the hospitals was through the Poor-law infirmaries. In conclusion, Mr. Chamberlain pointed out that the estimates of his department had been reduced in two years by nearly £4,750,000. He thought that they had almost got to the end of reduction. It would really be impossible to make further savings without trenching on services which in the public interests ought not to be curtailed.

Sir **KINGSLEY WOOD** said some £8,250,000 per annum had been paid to the 12,000 odd doctors on the panel under the Insurance Acts. Since the Act had been put into force £53,000,000 had been paid to them. He believed, and he had no doubt the Minister believed, that in very many respects the insurance medical service could be very greatly improved. One of the great defects was that only about half the general practitioners of the country had undertaken service under the Act. Large numbers of doctors might have big private practices, but he believed that there were also a very large number who had professional objections to serving under this administration, and they would never get a much more perfect service until they were able to attract a good many more medical men and induce them to take service. He made no general indictment against the profession, but they knew that there was a great body of complaints about the present service. There were far too many patients on doctors' panel lists. There were some 11 per cent. of the panel practitioners who had between 2000 and 3000 patients and 3 per cent. who had over 3000 patients. That called for immediate attention and remedy. When most of these medical men had a private practice as well, how on earth they could give proper attention to either practice he could not understand. His suggestion was that insured persons should be able to change their doctor at any time after reasonable notice. He did not think that the insured patient was getting the same or as good treatment as the private patient, and yet he was certainly entitled to it. The trade union which looked after the interests of the medical men in this country had issued a document counselling the members of their Association as to what they were to do if the Minister of Health did not accede to their demands as far as remuneration was concerned. That document, as he understood it, said that in certain events unless the Minister came to terms with the medical profession they would decline to carry on and engage in the service of the Act. He hoped that his right hon. friend would take no notice of such tactics, because he believed he would have behind him the whole of the country in resisting that kind of method from a body of men from whom they expected better things.

Sir **GEORGE BERRY** emphasised the importance of milk sterilisation, which he said was compulsory in some countries. He agreed that vaccination was essential, and that it was criminal to neglect it. He would like to see the voluntary system continued. It attracted the best class of medical men. He had always been an opponent of the panel system, not so much on account of the system itself as because of the way it was worked.

Dr. **WATTS** said that in regard to the small-pox epidemic in Gloucester and certain difficulties of diagnosis he thought that was one of the strongest arguments in favour of vaccination. In his younger days no medical man would have mistaken chicken-pox for small-pox. Labour Members and others made a great point of improved sanitation in regard to the decrease in small-pox. To a certain extent and degree that was perfectly true, but it was not the whole story. Scarlet fever, measles, and small-pox had been subjected to exactly the same sanitary conditions: but whereas the first two were as prevalent to-day as they were formerly, small-pox up to the last year or two had practically died out in this country. He was not asking for fresh legislation, but merely that the law as it existed should be carried into effect. Dr. Watts referred to the danger that within a very few weeks Mr. Spahlinger's establishment and his apparatus would be sold. He wished that rather than spend hundreds of thousands a year on sanatoria the Minister of Health would devote a few thousand pounds to helping Mr. Spahlinger. As regarded the panel service, while he had been a bitter opponent of the system, and he granted that in the early days the work was bad, to-day he was of opinion that the work was cheerfully, well, and efficiently done. There might be regrettable cases here and there—there must be black sheep everywhere—but on the whole he thought the practitioners were giving good service.

Major **MALLOY** said as a doctor who had never had anything to do with national insurance, as far as his experience went, and it was a pretty large one, the work done by the panel doctors was, as a rule, extremely good, and vastly superior to anything that obtained under the old dispensation. The hon. gentleman quoted a series of statistics to show the grave rise in the number of deaths from cancer, and urged the importance of cancer research. There was a great deal of danger in relying upon the generosity of the charitable and the frightened, because that was a precarious source of income at any time. Most of the men who did the best work in the laboratories throughout the country did not get as good wages as a first-rate chauffeur. The money went in the expense of apparatus and in costly experiments which had to be continued over long periods. He thought the Ministry of Health should not only be the mainspring but the master of any efforts made in this direction.

Mr. **NEVILLE CHAMBERLAIN**, replying to the debate, said that he agreed that the panel system, whatever might have been its defects and faults, had done a very valuable service, and had done much to raise the standard of medical attendance among the poorer classes of the people. He thought it had come to stay. At the same time every effort would be made to improve the service. In view of the fact that the present arrangement for the remuneration of the doctors came to an end in December, 1924, it was necessary before settling new terms to discuss with the doctors the arrangements of the service. A certain amount of discussion had taken place already. One subject was the limitation of the panel. Another, that there should be no private fees paid for services coming within the scope of the contract. Another was greater freedom in the choice of doctors than at present, and one more, of considerable importance, was that they should be able to secure that proper records were kept of each case. It was very important that this should be done, so that there should be in existence some records of the medical history of the patient. And that also would be valuable when the patient was changing his medical practitioner. When they had some agreement on various points, then they would have to go into the question of remuneration, and he could give his hon. friends the assurance that this matter would be discussed in the House sooner or later, very probably in the course of the autumn session, because he thought it was most likely that further legislation would be necessary in order to put into operation the new arrangement to which they might come. As regarded the Spahlinger treatment, he understood that a movement was going on for the raising of a sum of money privately which, if successful—as he had some reason to hope it might be—would enable Mr. Spahlinger to produce his remedies in sufficient quantities to be available for experiment, and he would then send a supply over here, where they would be handed to the Ministry for examination. The process discovered by Dr. Dreyer, as to which they had much more complete information, was very encouraging in its results. It was the policy, however, of the Ministry to test out any remedy submitted to them which seemed at all hopeful. As to the new School of Hygiene, plans had been prepared and a site chosen near the University buildings. The school would be affiliated to the University of London, but it would be governed by a body for which a charter of incorporation was to be sought, and in the meantime the work would be carried on by a transitional executive committee with the concurrence of the Rockefeller Institute. That committee, of which he was ex-officio chairman, had to consider the possible amalgamation or coöperation with similar institutions; it would go on with the preparation of plans and probably begin the building of the institution itself. But, most important of all, it had to proceed with the appointment of a director. They hoped to be able to make an appointment before very long. With regard to the recommendations of the Cobb Committee in connexion with lunacy, there were two lines of progress which were engaging his attention. One was the prosecution of research into all forms of mental disease, which had been taken up with considerable enthusiasm by a number of local authorities; the other line was the treatment of incipient cases without certification. The Mental Treatment Bill attempted to make some progress in that direction.

The Vote was agreed to.

Pensions Disability Committee.

Mr. Pielou asked the Minister of Pensions whether he could inform the House the composition of his Pensions Disability Committee; whether this Committee's findings had ever been published; and, if not, whether he would undertake to publish the result of the work of this Committee, especially that part that concerned the recommendations made to the doctors on the special boards in connexion with the examination of pensions for final awards.—Major Tryon replied: The Disability Committee is composed of the Presidents of the Royal Colleges of Physicians and Surgeons and of other distinguished physicians and surgeons, together with the chief medical officers of my department. The recommendations of the Committee with regard to the medical considerations which should be taken into account in determining the assessment of special classes of disability, in connexion both with conditional and final awards, are issued from time to time to all medical boards and medical officers concerned in the assessment of pensions. It would not be to the public advantage, in my opinion, to make a general publication of these recommendations of the Committee, which are of a purely technical character and deal with such questions as symptoms and diagnosis.

Changes in Pensions Headquarters in the North.

Mr. Albert Alexander asked the Minister of Pensions whether it was proposed to amalgamate the Yorkshire regional headquarters of the Ministry with the northern regional headquarters, and to close the regional headquarters at Leeds; and, if so, what were the reasons for the proposed change. Similar questions were asked by Mr. F. Jowett and Sir J. Butcher.—Major Tryon replied: The amalgamation of the northern and Yorkshire regions has been decided upon as a measure of administrative reform. I wish to emphasise the fact that the pensioners in the neighbourhood of Leeds will not be adversely affected in any way by the change, as an area office and medical boards will continue to be maintained in that city. I should not be justified in maintaining the two regions as separate units in view of the administrative economy and advantages which will result. The total staff in the Yorkshire regional headquarters, which numbers less than 300, has shown a decrease of 75 during the past six months, and will continue to decrease. It is proposed to effect the transfer gradually in the autumn, and I hope that it will be possible to house the two staffs in the existing premises at Newcastle without removing the area office. I understand that the Office of Works have other premises available for housing the income-tax office.

Nationality of Pension Doctors.

Mr. Becker asked the Minister of Pensions if, seeing that Scotland, Wales, and Ireland insisted that doctors appointed by the Ministry were of their own nationality, he would see that, in future, the doctors appointed in England should be English; and would he give preference in selecting these medical men to ex-Service doctors.—Major Tryon replied: The assumption on which this question is based is not correct. In making these appointments the first consideration is efficiency and, subject to that, it is and always has been the policy of the Ministry to give preference to those who have served. I may add that 91 per cent. of the whole-time medical officers employed by my department have served.

Medical Examinations in Nottingham.

Mr. Hayday asked the Minister of Pensions where it was proposed to medically examine the aged dependents of deceased Service men who were resident in Nottingham and its vicinity; and whether arrangements would be made for them to be examined at their own homes or in proximity thereto.—Major Tryon replied: The existing arrangements, which will be continued, provide for these examinations to be made at area headquarters, Nottingham, or at the homes of the applicants when they are not in a condition to travel.

Pitch Cancer.

Mr. David Williams asked the President of the Board of Trade the number of men certified as suffering from pitch cancer by those engaged in the manufacture of pitch and patent fuel during the past five years; how many had died of this disease during the same period; and how many employed in those industries had died in the same period from other forms of cancer; and whether, in view of the growth of this disease, he would make it obligatory on the manufacturers of these commodities to use mechanical appliances in the handling of pitch wherever possible.—Mr. Bridgeman (Home Secretary) replied: The numbers of men reported to the Factory Department as suffering from this disease during the five years 1918 to 1922 were as follows:—In 1918, 23; in 1919, 10; in 1920, 25; in 1921, 18; and in 1922, 15. No fatal cases were reported in 1918 to 1920; two were reported in 1921, and one in 1922. Before 1920 the disease was not compulsorily notifiable under the Factory Act, but cases were notified under a voluntary arrangement. As the hon. Member will observe, the figures do not indicate any growth in the incidence of this disease. I regret that no information is available to show the number of deaths in these industries during the period in question from other forms of cancer. As regards mechanical appliances, I understand that these are generally used when practicable, but that they can only be used in a few operations. I am advised that the most effective precautions against this disease are great attention to personal cleanliness and periodic medical examination, and that facilities to enable the worker to take these precautions have been arranged for at the instance of the Factory Department at all the works concerned.

MONDAY, JULY 2ND.

Panel Doctors' Certificates.

Mr. Lowth asked the Minister of Health whether he had received any communications from Poor-law guardians or other bodies or persons respecting the acceptance or otherwise of panel doctors' certificates for Poor-law relief cases; and whether he would issue such instructions to Poor-law authorities that panel doctors' certificates might be accepted.—Mr. Neville Chamberlain replied: The reply to the first part of the question is in the negative, and, as at present advised, I see no occasion for the revision of the existing regulations on this subject.

Cancer Mortality.

Commander Oliver Locker-Lampson asked the Minister of Health if, having regard to the increasing prevalence of and mortality from cancer in the British Isles, he would consider the advisability of initiating in every local area under his control special machinery to investigate and, if possible, discover its cause and cure, the expenses of such machinery to be defrayed by a local rate.—Mr. Neville Chamberlain replied: I am giving attention to the increasing prevalence of and mortality from cancer and the action which central or local public health authorities may be able to take in the investigation of the cause and cure of this disease. As at present advised, however, I do not consider that the establishment in every area of special machinery financed out of local rates as suggested in the question would be desirable.

Arm-to-Arm Vaccination.

Mr. Rhys Davies asked the Minister of Health whether he was aware that, at the present time, many medical practitioners still employed the arm-to-arm method of vaccination in private practice; and whether, in view of the serious risks attending that practice, he would consider the desirability of making representations to the medical profession on the matter.—Mr. NEVILLE CHAMBERLAIN replied : The answer to the first part of the question is in the negative. My information is that comparatively few medical practitioners now employ this method of vaccination, and I scarcely think it necessary to make representations to the medical profession on the matter.

Legacies to Hospitals.

The Finance Bill was considered on Report.

Viscount EDNAM moved a new clause providing that legacy and succession duty should not be leviable or testimentary bequests made to hospitals carried on in the public interest. He said that while the ordinary income of the hospitals had increased since 1913 by 67 per cent., ordinary expenditure had increased by 137 per cent. He was informed by the British Hospitals Association and the King Edward's Fund that the average cost to the Exchequer of the concession would not exceed £130,000. If the voluntary system broke down the whole of this extra expense would be thrown upon the State.

Major CADOGAN seconded. He said that so long as the voluntary system was able to increase the amount of money raised on behalf of the hospitals the House ought to encourage the system, which not only saved the tax-payer something between £3,000,000 and £4,000,000 a year, but undoubtedly functioned far more efficiently than any State agency could possibly do.

Sir T. INSKIP (Solicitor-General), replying to the debate, said that at the most sanguine estimate a sum of £200,000 was involved and that was spread over 950 hospitals. It was not because the Government could not afford this sum that they were unable to grant this concession, but mainly because they thought it was impossible to make distinctions between one charity and another, and that if the hospitals did work for the State, the proper course was for a grant to be made from State funds.

Viscount EDNAM said that the hospital authorities for whom he spoke did not wish to divide against the Government, and therefore he asked leave to withdraw his new clause.

The Labour party opposed the withdrawal of the clause, which was negatived on a division by 243 votes to 153—majority 90.

THE LANCET: SUBSCRIPTION RATES.

		£	s.	d.
INLAND	One Year	£2	2	0
	Six Months	1	1	0
	Three Months	0	10	6

POSITION PAGES.—Terms on application.

A COMFORT FOR INVALIDS.—The *Preston Guardian* for June 23rd contains an illustration and description of a combination of chairs and simple accessories which should prove useful to the invalid and to the infirm. The combination has been devised by Sir Charles Brown, F.R.C.S., F.R.C.P., who is nearing 87 years of age and has been compelled to sleep downstairs for the past 18 months. The basis of the arrangement is an American rocking chair, which can be fixed in either the extreme upright or horizontal position by means of a large wedge. The companion chair, which can be used in the day time as an ordinary chair, extends the seat of the rocking chair, and with the aid of cushions, bed-clothes, and a hot-water bottle, a comfortable bed can be devised. An arrangement of cords allows the invalid to arrange the hot-water bottle according to his wishes. A simple table is provided for taking meals.

Appointments.

FELDMAN, W. M., M.D. Lond., F.R.S. Edin., has been appointed Physician to St. Mary's Hospital for Women and Children, Plaistow.

KEITH, F. L., M.D., Ch.B. Aberd., D.P.H., Medical Officer of Health for St. Pancras.

Manchester Royal Infirmary: TWINING, E. W., M.R.C.S., L.R.C.P. Lond., Radiological Registrar; and NEWELL, R. L., M.D. Manch., F.R.C.S. Eng., Assistant Surgical Officer.

Vacancies.

For further information refer to the advertisement columns.

Barbados General Hospital.—Jun. Res. S. £250.

Barnstaple, North Devon Infirmary.—H.S. £170.

Belfast, Queen's University.—Lecturer in Pharmacology. £450.

Belgrave Hospital for Children, Clapham-road, S.W.—Hon. Radiologist. 50 guineas.

Bristol Mental Hospital.—M.O. and Pathologist. £400.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Gt. Barrow, near Chester.—Med. Supt. £800.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Physician.

Dreadnought Hospital, Greenwich, S.E.—H.P. £150.

East African Medical Service.—M.O. £600.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Part-time Pathologist. £400.

East-street Welfare Centre, Walworth, S.E.—Hon. Clin. Assts. Hon. P. for Infants.

Gloucester City.—M.O.H. £1000.

Guy's Hospital Dental School.—Senior Dental O. and Clin. Tutor. £300.

Hospital for Consumption and Diseases of the Chest, Brompton.—H.P.

Hove Hospital.—Res. M.O. £200.

King's College Hospital, Denmark Hill, S.E.—Second Asst. Radiologist. £300.

London County Mental Hospital Service.—Seventh Asst. M.O. £440.

Manchester Royal Infirmary.—Asst. Director to Clin. Lab. £350.

Miller General Hospital for South-East London, Greenwich-road, S.E.—H.P. £150.

Northampton General Hospital.—Two H.S.'s. Each £200.

Preston, Lancs, County Mental Hospital, Whittingham.—Locum Tenens M.O. £8 8s. per week.

Queen Mary's Hospital for the East End, E.—Hon. M.O. for Radio-Electro-Therapeutic Dept.

Royal Dental Hospital, London.—Hon. Asst. Dental Surg.

Royal Naval Medical Service.—Surgeon-Lieutenants.

Salford Union Infirmary, Hope, Pendleton, near Manchester.—Third and Fourth Asst. Res. M.O.'s. Each £200.

Sheffield Royal Hospital.—Cas. O. Hon. Surg. Asst. Cas. O.

Stoke-on-Trent County Borough.—Asst. M.O. £500.

West African Medical Service.—M.O. £660.

Willesden Urban District Council.—Two Asst. M O.'s. £500 and £600 respectively.

Wrexham Infirmary.—H.S. £150.

Births, Marriages, and Deaths.

BIRTHS.

ALEXANDER.—On June 29th, at Cade House, Riverhead, Sevenoaks, the wife of J. Finlay Alexander, M.A., M.D. Camb., of a daughter.

KERR.—On June 27th, at Baghdad, Iraq, the wife of J. Fraser Kerr, L.R.C.P. & S. Edin., Civil Surgeon, Hillah, Iraq, of a daughter. (By cable.)

SPERO.—On June 26th, at Connaught-square, W., the wife of Dr. G. E. Spero, of a daughter.

MARRIAGES.

DONKIN—BATES.—On June 27th, at St. James', Paddington, Sir Bryan Donkin, M.D., F.R.C.P., of London, to Marie Louise, widow of Isaac Bates, of Belfast, and daughter of the late William Preston, of Wilmington, North Carolina, U.S.A.

HALE—COLES.—On June 26th, at Watford Parish Church, John Hale, M.A., M.B. Camb., to Elsie Ledbrooke, daughter of Mr. and Mrs. Walter S. Coles, of Oxhey View, Watford, and Standean, Sussex.

DEATHS.

LIDDON.—On June 26th, at Silver-street House, Taunton, Edward Liddon, M.D., aged 92.

PROUDFOOT.—On June 21st, at St. Clair-street, Kirkcaldy, Scotland, suddenly, Robert Butter Proudfoot, M.D., in his 65th year.

RATTRAY.—On July 2nd, suddenly, at Pemberton-gardens, Upper Holloway, Patrick Whyte Rattray, F.R.C.S., in his 64th year.

WHITTING.—On June 25th, Charles Edward Whitting, M.A., M.B. Camb., of Buxton, aged 25 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

medical history of the patient. And that also would be valuable when the patient was changing his medical practitioner. When they had some agreement on various points, then they would have to go into the question of remuneration, and he could give his hon. friends the assurance that this matter would be discussed in the House sooner or later, very probably in the course of the autumn session, because he thought it was most likely that further legislation would be necessary in order to put into operation the new arrangement to which they might come. As regarded the Spahlinger treatment, he understood that a movement was going on for the raising of a sum of money privately which, if successful—as he had some reason to hope it might be—would enable Mr. Spahlinger to produce his remedies in sufficient quantities to be available for experiment, and he would then send a supply over here, where they would be handed to the Ministry for examination. The process discovered by Dr. Dreyer, as to which they had much more complete information, was very encouraging in its results. It was the policy, however, of the Ministry to test out any remedy submitted to them which seemed at all hopeful. As to the new School of Hygiene, plans had been prepared and a site chosen near the University buildings. The school would be affiliated to the University of London, but it would be governed by a body for which a charter of incorporation was to be sought, and in the meantime the work would be carried on by a transitional executive committee with the concurrence of the Rockefeller Institute. That committee, of which he was ex-officio chairman, had to consider the possible amalgamation or coöperation with similar institutions; it would go on with the preparation of plans and probably begin the building of the institution itself. But, most important of all, it had to proceed with the appointment of a director. They hoped to be able to make an appointment before very long. With regard to the recommendations of the Cobb Committee in connexion with lunacy, there were two lines of progress which were engaging his attention. One was the prosecution of research into all forms of mental disease, which had been taken up with considerable enthusiasm by a number of local authorities; the other line was the treatment of incipient cases without certification. The Mental Treatment Bill attempted to make some progress in that direction.

The Vote was agreed to.

Pensions Disability Committee.

Mr. PIELOU asked the Minister of Pensions whether he could inform the House the composition of his Pensions Disability Committee; whether this Committee's findings had ever been published; and, if not, whether he would undertake to publish the result of the work of this Committee, especially that part that concerned the recommendations made to the doctors on the special boards in connexion with the examination of pensions for final awards.—Major TRYON replied: The Disability Committee is composed of the Presidents of the Royal Colleges of Physicians and Surgeons and of other distinguished physicians and surgeons, together with the chief medical officers of my department. The recommendations of the Committee with regard to the medical considerations which should be taken into account in determining the assessment of special classes of disability, in connexion both with conditional and final awards, are issued from time to time to all medical boards and medical officers concerned in the assessment of pensions. It would not be to the public advantage, in my opinion, to make a general publication of these recommendations of the Committee, which are of a purely technical character and deal with such questions as symptoms and diagnosis.

Changes in Pensions Headquarters in the North.

Mr. ALBERT ALEXANDER asked the Minister of Pensions whether it was proposed to amalgamate the Yorkshire regional headquarters of the Ministry with the northern regional headquarters, and to close the regional headquarters at Leeds; and, if so, what were the reasons for the proposed change. Similar questions were asked by Mr. F. JOWETT and Sir J. BUTCHER.—Major TRYON replied: The amalgamation of the northern and Yorkshire regions has been decided upon as a measure of administrative reform. I wish to emphasise the fact that the pensioners in the neighbourhood of Leeds will not be adversely affected in any way by the change, as an area office and medical boards will continue to be maintained in that city. I should not be justified in maintaining the two regions as separate units in view of the administrative economy and advantages which will result. The total staff in the Yorkshire regional headquarters, which numbers less than 300, has shown a decrease of 75 during the past six months, and will continue to decrease. It is proposed to effect the transfer gradually in the autumn, and I hope that it will be possible to house the two staffs in the existing premises at Newcastle without removing the area office. I understand that the Office of Works have other premises available for housing the income-tax office.

Nationality of Pension Doctors.

Mr. BECKER asked the Minister of Pensions if, seeing that Scotland, Wales, and Ireland insisted that doctors appointed by the Ministry were of their own nationality, he would see that, in future, the doctors appointed in England should be English; and would he give preference in selecting these medical men to ex-Service doctors.—Major TRYON replied: The assumption on which this question is based is not correct. In making these appointments the first consideration is efficiency and, subject to that, it is and always has been the policy of the Ministry to give preference to those who have served. I may add that 91 per cent. of the whole-time medical officers employed by my department have served.

Medical Examinations in Nottingham.

Mr. HAYDAY asked the Minister of Pensions where it was proposed to medically examine the aged dependents of deceased Service men who were resident in Nottingham and its vicinity; and whether arrangements would be made for them to be examined at their own homes or in proximity thereto.—Major TRYON replied: The existing arrangements, which will be continued, provide for these examinations to be made at area headquarters, Nottingham, or at the homes of the applicants when they are not in a condition to travel.

Pitch Cancer.

Mr. DAVID WILLIAMS asked the President of the Board of Trade the number of men certified as suffering from pitch cancer by those engaged in the manufacture of pitch and patent fuel during the past five years; how many had died of this disease during the same period; and how many employed in those industries had died in the same period from other forms of cancer; and whether, in view of the growth of this disease, he would make it obligatory on the manufacturers of these commodities to use mechanical appliances in the handling of pitch wherever possible.—Mr. BRIDGEMAN (Home Secretary) replied: The numbers of men reported to the Factory Department as suffering from this disease during the five years 1918 to 1922 were as follows:—In 1918, 23; in 1919, 10; in 1920, 25; in 1921, 18; and in 1922, 15. No fatal cases were reported in 1918 to 1920; two were reported in 1921, and one in 1922. Before 1920 the disease was not compulsorily notifiable under the Factory Act, but cases were notified under a voluntary arrangement. As the hon. Member will observe, the figures do not indicate any growth in the incidence of this disease. I regret that no information is available to show the number of deaths in these industries during the period in question from other forms of cancer. As regards mechanical appliances, I understand that these are generally used when practicable, but that they can only be used in a few operations. I am advised that the most effective precautions against this disease are great attention to personal cleanliness and periodic medical examination, and that facilities to enable the worker to take these precautions have been arranged for at the instance of the Factory Department at all the works concerned.

MONDAY, JULY 2ND.

Panel Doctors' Certificates.

Mr. LOWTH asked the Minister of Health whether he had received any communications from Poor-law guardians or other bodies or persons respecting the acceptance or otherwise of panel doctors' certificates for Poor-law relief cases; and whether he would issue such instructions to Poor-law authorities that panel doctors' certificates might be accepted.—Mr. NEVILLE CHAMBERLAIN replied: The reply to the first part of the question is in the negative, and, as at present advised, I see no occasion for the revision of the existing regulations on this subject.

Cancer Mortality.

Commander OLIVER LOCKER-LAMPSON asked the Minister of Health if, having regard to the increasing prevalence of and mortality from cancer in the British Isles, he would consider the advisability of initiating in every local area under his control special machinery to investigate and, if possible, discover its cause and cure, the expenses of such machinery to be defrayed by a local rate.—Mr. NEVILLE CHAMBERLAIN replied: I am giving attention to the increasing prevalence of and mortality from cancer and the action which central or local public health authorities may be able to take in the investigation of the cause and cure of this disease. As at present advised, however, I do not consider that the establishment in every area of special machinery financed out of local rates as suggested in the question would be desirable.

Arm-to-Arm Vaccination.

Mr. RHYS DAVIES asked the Minister of Health whether he was aware that, at the present time, many medical practitioners still employed the arm-to-arm method of vaccination in private practice; and whether, in view of the serious risks attending that practice, he would consider the eye—to serve as an example. A critic of Darwin said he would as soon believe that a handful of words falling at random on a table could arrange themselves in the form of a perfect poem as that the parts of the eye had been assembled by chance. In 1903 Dr. W. H. Lewis commenced a series of experiments on developing tadpoles of a particular species, and found that when the optic cup, which forms the retina, grows out from the brain it comes against the overlying ectoderm or skin of the embryo. When the optic cup makes this contact the overlying ectoderm begins to form a lens. By transplanting the optic cup, Dr. Lewis found it had the power to compel the overlying ectoderm of any part to form a lens. Embryologists, by adopting the methods used by bacteriologists, have been able to demonstrate that some tissues of the embryo exercise controlling influences over other tissues. The pattern in which epithelial cells grow is altered when cells of a connective tissue nature are added. It is clear that we are now on the threshold of a new field of knowledge—one which presents us with a vista of an infinite complexity of mechanisms which regulate development and growth. The manner in which new and useful adaptations come into existence, or are evolved, will become apparent as we get to know the nature of such mechanisms.

We have known for many years that developing nerve cells have the power to send out processes which effect distant contacts with exceeding accuracy. But the knowledge that groups of neuroblasts have a power of migrating is new; and is, to a large extent, the result of researches carried out by Dr. Kappers of Amsterdam. These migrations affect groups of nerve cells concerned in a common function; such a group moves towards a site which is advantageous for the purpose it is to serve in the mechanism of the central nervous system. A change in position of this kind may be described as purposive. What influence propels or attracts these nerve groups or centres towards new sites we do not know, but the power and inclination to migrate during embryological stages are clearly part of the machinery of the evolution of the brain. The peculiar adaptational mechanisms of man's body are best studied in connexion with the development of his muscles. The musculature of the face and of expression of the higher primates represents a graduated series. The degree to which the facial muscles of man are differentiated is but the culminating phase of a series of advancing stages. Differentiation of the muscles of expression keeps time with the elaboration of the brain. The bud or embryonic nucleus which gives rise to the muscles of the face is formed locally below the ear from the substance of the hyoid arch. From this sub-auricular point the embryonic muscle cells spread outwards or migrate into all parts of the face, head, and neck, each group reaching and arranging themselves in their proper stations. Clearly the migratory power of young muscle cells—whatever be the nature of the influence which controls them—is part of the machinery of adaptation and evolution. The latissimus dorsi is another muscle which illustrates the migratory power of embryonic muscle cells; in this case they migrate from the neck to the loins.

The power of apparent automatic action seen in all kinds of cells in the early development of embryonic tissues is lost as fœtal stages of growth are reached. Certain wandering cells, like leucocytes, retain this archaic property of automatism. Bone cells, too, retain a high degree of adaptability to new conditions. How they react so as to buttress a bending bone is well known. But bone cells, and also cartilage cells, when they proceed to lay down the outlines of bones and joints, must be coördinated in their action to an exceedingly fine degree. For when they have completed their work, as in the bones of the hand, a harmoniously working contrivance has been produced. The properties of embryonic bone and cartilage cells constitute part of the machinery of evolution.

It is when we seek for the evolutionary machinery which has given rise to such a delicately balanced mechanism as is seen in the human spine that we realise how complex such a machinery must be. The bone cells which are laying down the levers attached to each vertebra, the muscle cells arranging themselves to act on these levers, the nerve cells grouping themselves in the spinal cord, and in the brain in order to coördinate the action of the vertebral muscle, are all working towards a common, harmonious end—the maintenance of the human spine in the walking posture. Clearly any adaptational change must affect every one of the millions of diverse units concerned in this functional result. That the human spine has been evolved there can be no doubt, but where is the machinery which transformed the ape's spine into that of man?

The Theory of Hormones.

I know of only one theory which assists one to explain such evolutionary occurrences, and that is the theory of hormones as propounded by Starling in 1905. He was in no doubt as to the nature of the discovery he had made. He clearly realised that hormones formed the basis of all evolutionary progress; hormones are the means by which social life amongst the oldest and simplest of unicellular organisms is rendered possible; it is an elaboration of this system of hormonic intercommunication which makes a colony of sponge zooids possible. In the assemblage of cells which constitute the body of the human embryo we see a colony apparently governed by a system of hormones—automatic in its constitution, yet so involved and intricate that it will take centuries of research to unravel the manner of its working. The key to evolution is a knowledge of how one group of embryonic cells influences and compels another group to produce a functional result. The means used are chemical missives or hormones.

The hormone system of government—like the nervous system, which is a structural extension of the older hormone mode of government—is founded on a reflex basis. Everyone knows that, if the muscular system of a man be exercised or trained, all the other systems of his body—his bones, lungs, heart, arteries, organs of digestion also undergo a responsive growth. We cannot explain such a response unless we postulate a hormone system—one which supposes that active muscles throw out missives, and that these missives evoke a reflex growth response in structures like the bones, heart, and lungs, which are accessory in action to the muscles. Acromegaly is a morbid manifestation or disorder of the mechanism which brings about the adaptational growth-response of exercise and of training. In acromegaly we find that the pituitary gland is always involved. This gland is apparently one of the chief coördinating centres—a sort of hormone brain—of the archaic coördinating system. Missives issuing from contracting muscles evoke reflexly from the pituitary certain substances which, passing into the circulation, act on accessory structures, such as the heart, lungs, and bones.

A specimen in the Museum of Charing Cross Hospital throws a clear light on the growth-regulating machinery of the human body. It is the skull of a boy who died after an operation to arrest the growth of a tumour-like swelling on the right side of his face. As may be seen from the specimen, the over-growth is most sharply and definitely limited to one functional system of the face and head—that which is concerned in mastication. On one side the teeth, jaws, and the bony struts which support the jaws, all the parts which give support to, or are acted on, by the muscles of mastication, are markedly overgrown. The condition was congenital. We cannot explain such manifestations—for the case cited is by no means unique—unless we suppose that the growth mechanisms which regulate the assembling and deploying of cells in the embryo is constituted on a functional basis. Structures concerned in a common function are correlated by a common growth mechanism.

Automatic Properties Retained by Embryonic Cells.

John Hunter gave utterance to a great truth when he said that there remained in our vascular and bony tissues the automatic properties to be seen in the lowest forms of organised life, such as the hydra. In the formative period of the human embryo—in the phase when adaptational contrivances are being worked out in the heart, brain, bone, and muscle—the embryonic cells still retain many of the automatic properties of primitive unicellular organisms. Herbert Spencer was also right when he said that if we would understand the evolution of government and adaptation in the developing animal body, such as that of man, we would do well to study first the evolution of government in a people rising from barbarism to civilisation. In the earlier stages of the evolution of human society we see that the machinery of government is represented by the automatic working of a herd-instinct—an instinct which tends to work for the good of the community. The instinct is biased in the direction of producing functional or effective results. We have to study what in our ignorance we must call the herd-instincts of that vast community which makes up the body of a human embryo, if we would understand how the structural contrivances of the human body have been evolved. I, for one, believe with Huxley that the government which rules within the body of the embryo proceeds uninfluenced by the occurrences which affect the body of the adult. Man has come by his great gifts—his brain, his upright posture, his nimble hand—not by any effort of his own; he has fallen heir to a fortune for which neither he nor his ancestors have laboured. The human body is the vehicle of a colossal and absorbing evolutionary experiment.

HEALTH CONDITIONS IN SOMALILAND.

THE medical report for 1921 shows that during the year 4492 cases of tropical ulcers were recorded, as compared with 4651 in 1920, and cases of scurvy fell from 55 to 22. Of malaria 145 cases were reported, as against 257 in the previous year. The subtertian is the commonest type identified. A steady decline in malaria can be noted year

Notes, Comments, and Abstracts.

TELEOLOGY AND EVOLUTION.[1]

BY SIR ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG., F.R.S.,
CONSERVATOR OF THE MUSEUM AND HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TELEOLOGY, a word so familiar to the generation which read the works of Archdeacon Paley, has disappeared from the vocabulary of men of science. The things for which the word stood, the numerous contrivances to be seen in the human body, still remain; indeed, as we get to know the human body better its contrivances become not less, but more wonderful. Most people believed that Darwin had explained how such contrivances had arisen, but Huxley, although convinced that Darwin's main thesis was true, held a peculiar opinion as to the exact manner in which useful contrivances or adaptations came into existence.

The Doctrine of Evolutionary Predestination.

Any opinion held by Huxley regarding the structure of man was of real value. He had been a student of human anatomy at two periods of his career—first when studying medicine at Charing Cross Hospital, from 1842 to 1846, and then later, during the crisis raised by Darwin's "Origin" in the sixties of last century, he again made the evolution and nature of man his main theme of interest. In 1876, when he was in his fifty-first year and at the zenith of his intellectual ability, he had to lecture in Glasgow, and selected the hand as the theme of his discourse—a structure which Sir Charles Bell made the subject of a Bridgewater treatise. The old teleologists regarded the contrivances of the hand as of supernatural origin. Huxley admitted the excellency of its contrivances, but held they were neither the result of supernatural interposition nor were they functionally acquired characters. He held there was no evidence to support the belief that a child's hand could be influenced in size or action by hard manual labour on the part of its parents. "To be a teleologist" he said, "and yet accept evolution, it is only necessary to suppose that the original plan was sketched out and that the purpose was foreshadowed in the molecular arrangements out of which animals have come." Here we find Huxley, the sanest and most gifted of men, preaching a doctrine of evolutionary predestination. For if we apply this abstract declaration to the hand, foot, or brain of man, it simply means that in Huxley's opinion the designs which have blossomed into existence during the evolution of our brains, feet, and hands, were already germinating in the corresponding parts of man's simian ancestor.

Strange as it may seem to laymen, this doctrine of an evolutionary predestination is held by most of the men who have traced the history of animals through long geological ages by the study of fossil remains. The evidence which accumulates relating to the origin of man's most outstanding features favours this view. Many of man's newest structural acquisitions represent phases which are transitional in the young of anthropoid apes. The hairlessness of the skin of mankind, the fairness of the complexion of Europeans, man's relatively big head poised on a small neck, a large brain, a small face and jaws, a human proportion in the segments of the limbs and in the joints of the fingers and toes are acquisitions of this kind. New human characters are foreshadowed in developmental stages passed through by apes. And that these developmental characters are new and have never been perpetuated into an adult stage until man's evolution took place, there can be no doubt. All the fossil primates of which we have any knowledge are marked, not by these fœtal characters, but by features of a reverse kind. Development is a double process—old ancestral features are recalled and new features are introduced. Business men know that capital is necessary for the development of a new and large undertaking. Nature made this discovery long ago; she places sufficient capital at the disposal of the fœtus of man and anthropoid to carry them through the nine months which are spent in the womb, and it is during this latent, preparatory period that new designs are introduced and elaborated.

If Huxley is right, then man's destinies lie hid in the potentialities of his germ-plasm. There may be some consolation in knowing that there is nothing we can say or do, eat or drink, which will alter our evolutionary destiny—except in so far as we may voluntarily select and favour certain types of man as breeders do. If we cannot compel Nature to produce the type of man we may be in search of, we can, if we are so minded, favour one of the many types which Nature tends to produce.

Human Life a Continual Experiment.

But our main consolation would lie in this: we are attempting in these passing centuries one of the great experiments of human history. Perhaps the greatest revolution which has affected human life and evolution followed the discovery of the uses of fire and its application to the preparation of human food. The human body had then its nourishment presented to it in a state which no animal body had experienced before. In these modern days the conditions of human life have been again revolutionised; we abide in cities and live in houses; we work in heated factories, we breathe air laden with fumes of diverse kinds, we eat artificially prepared and concentrated foods, many of a novel kind; we drink beverages containing alkaloids which were unknown to our ancestors. We cannot claim that our bodies are escaping certain effects produced by modern methods of life. Nature has not made our bodies fool-proof. It would be a relief to know that the source from which the new generations of mankind issue was beyond any source of permanent contamination. But is it?

Transmission of Defect.

Darwin records the case of a cow in which the eye was injured when with calf. The calf was born with the corresponding eye small and blind. An identical case has been recently recorded of a mare; one eye was injured when she was pregnant and the foal was born with the corresponding eye small and blind. These are apparently not coincidences, for certain well-known experiments, which have been carried out lately by Guyer and Smith, throw light on how such an injury is transmitted. They injected rabbits with a substance which has a selective and destructive action on the lens of the eye; many of the progeny of such rabbits had small and defective eyes. They found that the defect thus produced was hereditary; it could be handed on by the male alone. Somehow the actual germ-plasm of these rabbits had been reached, and that element which is concerned with the formation of the eye had been permanently damaged. Professor Stockard induced permanent changes in the germ-plasm of guinea-pigs by treating one generation of them to extreme and prolonged doses of alcohol. Dr. J. G. Adami has summed up the evidence on this matter in his "Medical Contributions to the Study of Evolution."

Although ordinary injuries, such as the amputation of a limb or finger, the removal of the foreskin, the rupture of the hymen, the docking of horses, dogs, or sheep, produce no apparent effect on the progeny, yet it is clear that certain substances can reach and injure the germ-plasm in such a way as to induce permanent localised defects in the progeny. It is possible that certain defects—such as contracted palate, deformed jaws, the narrowing and margination of the nasal aperture, the tendency to flat-foot, and torsion of the spine, which are so common in present-day Englishmen and were so rare in their prehistoric ancestors, are due to toxic or other substances now circulating in our bodies. Is the prevalence of shortsightedness in modern civilised populations to be ascribed to such a cause? All one can say now of these defects is that they are of recent origin, and represent features which are new to the human body. No doubt the little use made by modern people of their teeth and jaws have something to do with the appearance of these changes in their faces, but disuse alone cannot explain them.

It is one thing to produce a definite and permanent lesion of the germ-plasm; it is quite another thing to influence the germ-plasm in such a way as to make it produce a useful or contrived modification of the eye, or of the hand, or of the foot. Take the human teeth, for example. Each upper tooth fits against, or should fit against, a counterpart in the lower jaw. Yet the crowns of the teeth, the articulating or opposing dental surfaces, are perfectly formed long before they come into use. When they do come into use they become worn and deformed, yet such abrasion leads to no change in the shape of the teeth of the progeny. A study of the teeth of man and apes shows that there is a mechanism which controls the kind of pattern and relative size and shape of all the teeth. When a dentition is undergoing evolutionary strengthening, or if it is undergoing a reduction, each tooth suffers a change which affects the whole dental series in an orderly manner. The machinery which regulates the formation and evolution of teeth is one which cannot be influenced by any act or habit on the part of the parent. As Huxley declared, there is no evidence to lead us to believe that purposive modifications of structure can be produced by use. What, then, is the mechanism of their production?

Complexity of Mechanism of Growth.

Since Darwin and Huxley wrote, our conception of the machinery which controls the development of the embryo—and the machinery of development is also the machinery of evolution—has undergone a great extension. Let us take the development of that highly teleological organ—the

Post-Graduate Lectures

ON THE

SURGERY OF THE THYROID GLAND.

LIBRARY

Delivered at the London Hospital on June 8th and 15th, 1923,

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON, LONDON HOSPITAL.

LECTURE I.*

THERE is hardly one, if indeed there is one, subject in medicine or surgery of which we can say that finality of knowledge has been reached. The inexactitude of our knowledge of the diseases of, or even of the normal condition of, the thyroid is especially noticeable, and the more we study this subject the more we realise how uncertain are our views and how we must be prepared to alter them as fresh evidence arises. It is manifestly impossible to discuss the whole subject in two lectures; I therefore propose to limit my remarks to the various forms of innocent overgrowth of the gland, for to such lesions surgical measures of treatment are most applicable. These overgrowths may for convenience be best classified as follows:—(*a*) Localised: adenomata and fibro-adenomata, cysto-adenomata, and pure cysts; (*b*) Diffuse: colloid goitre, adeno-parenchymatous goitre, and exophthalmic goitre or Graves's disease.

If such rare cysts as hydatids are excluded from the first group it will be found that all these lesions commence as pure adenomata; in the second group the adeno-parenchymatous is simply a combination of colloid goitre and adenomatous masses, although, as I shall show presently, there is a definite tendency for a colloid goitre to develop localised overgrowths. Hence, as Plummer has frequently insisted, there are really only three innocent overgrowths of the thyroid, although various combinations of such overgrowths frequently occur. These primary enlargements are adenomata, colloid goitre, and exophthalmic goitre.

ADENOMATA.

Pathology.

True adenomatous enlargements commence in a thyroid which is previously healthy and are definitely localised and encapsulated. This point must be emphasised because many of the localised overgrowths, especially those seen in *endemic* goitre and thus found in association with more diffuse changes, have a less well-defined capsule and are, in fact, often not adenomata at all. The true adenomata are frequently single, although not uncommonly two or three may be present. They occur in any part of the gland. In the early stages they form spherical masses of solid glandular tissue which show already a distinct fibrous capsule. They tend steadily to progress in size, but rarely reach the diameter of 1 inch without showing definite evidence of degeneration. The microscopic study of a small adenoma will show that it consists of vesicles lined by epithelium, cuboidal or flattened according to the size of the vesicle. These are much larger than normal, and may be 10 or 20 times the size of the vesicles seen in a healthy gland. In nearly all cases the characteristic feature is the irregularity in the size of the vesicles, many small vesicles being packed between those which are enlarged. As the vesicles increase the walls atrophy and the adjacent cavities run together. It therefore happens that an adenoma 1 inch or more in diameter nearly always shows areas of so-called colloid degeneration—that is to say, there are spaces perhaps *only* as large as a pea, perhaps 1 inch or more in diameter, which are filled with semi-fluid colloid material. This is the origin of the ordinary cystic degeneration of an adenoma, and in some cases the process may progress so far that the whole of the vesicular walls are destroyed and a pure cyst is left, formed of the original fibroid capsule and filled with fluid colloid material. During the destruction of the vesicular walls capillaries may be ruptured and hæmorrhage may take place into the cavity of the cyst. Hence the fluid is either brown in colour or is formed almost wholly of altered blood. At times the hæmorrhage is severe so that the cyst rapidly increases in size, and on removal is seen to contain a large quantity of blood. In the more chronic cases there is an increase of fibrous tissue in the capsule or in the septa. Such a change may be excessive, so that the adenoma in very large part is formed of fibrous tissue, giving rise to the so-called fibro-adenoma. At other times there are calcareous changes within the fibrous tissue, and it is not at all uncommon in old adenomata to find small areas which grate when the tissue is cut and which consist of a calcareous deposit, or sometimes indeed of true bone. This calcareous change may be so excessive that the whole capsule is converted into a stony membrane which does not collapse when the tumour is incised. Another very important and not infrequent change is the formation of the so-called thyrotoxic or fœtal adenoma. Plummer[24] was the first to direct attention to this condition, although Langhans[15] had previously laid considerable stress upon a condition which he described as proliferating goitre. In such fœtal adenomata a naked eye section will show that the tumour has a much more fleshy or granular appearance. In fact, the cut surface will much more resemble that of an exophthalmic goitre than of a normal thyroid. Microscopically it will be seen that the section is made up of solid masses of cells which are often small and embryonic in type, and if arranged in lobules show a very small amount of stroma between. Bloodgood[2] and Goetsch[10] have both called attention to the fact that in the normal thyroid there are two types of cell. There are those forming acini with a more or less definite basement membrane and certain interstitial epithelial cells which lie loosely between the acini. Meleney[23] has shown that it is these interstitial cells especially which are so increased in the formation of the fœtal adenomata. The importance of this change lies in the effects of such cellular overgrowth. McCarrison[16] regards these cells as reserve parenchymatous cells from which new acini are formed as required. In their more embryonic state they may, when they proliferate, not only give rise to hyperthyroidism, but may, indeed, closely resemble in appearance a carcinomatous change. The difficulty in making a differential diagnosis is increased by the fact that not infrequently this variety of tumour does in fact become true carcinoma. Speese and Brown[25] investigated a series of 28 cases of malignant disease and found that 19 of these arose in previous adenomata and that the average time that elapsed before the adenoma showed malignant changes was $12\frac{6}{10}$ years. It was interesting to note also that in five of these cases of carcinomata toxic manifestations of the adenoma were present before there was definite malignant change. Wilson[27] believes that practically all malignant tumours arise from this variety of fœtal adenomata. In a later communication he[28] investigated the complete literature of this subject and found that there were 193 malignant tumours in a series of 74,335 collected necropsies. Of 97 cases in the Mayo Clinic 50 were only diagnosed by pathological section after removal. Of a further 290 cases in the same clinic only 61 had not noticed a previous thyroid enlargement. He says that if the enlargements are due to circumscribed proliferation of the parenchymatous tissue they are adenomata. If they remain encapsulated and slowly degenerate they are benign. If they are associated with symptoms of slowly developing hypermetabolism with cardiac disturbances they are toxic non-exophthalmic goitre, the toxic adenomata of Plummer. If they continue to proliferate they penetrate their capsule, invade and metastasise, and are then malignant. He points out that histologically it may be almost impossible to differentiate the fœtal adenomata from the carcinoma. He therefore lays by year. There were 113 cases of relapsing fever, compared with 64 in 1920. The distinct form of this fever noted in a previous report as confined to Burao, and apparently carried by the bed-bug, has died out. There were recorded 32 cases of small-pox (all contracted outside the Protectorate), 82 of influenza, 132 of dysentery, 719 of syphilis, and 406 of gonorrhœa. There were 186 cases of tuberculosis with 21 deaths, as against 263 cases with 24 deaths in 1920. The decrease in poverty amongst the natives due to peaceful conditions and good seasons probably accounts for the decline in this disease. The health of European officials shows a considerable improvement. Only 14 Europeans were placed on the sick list (a percentage of 1·1 to the average number resident), and these cases all occurred in Berbera. The total number of patients admitted to hospitals was 1262, as against 1998 in 1920, whilst the out-patients numbered 19,119 as compared with 17,145.

---

*Lecture II. will appear in a forthcoming issue of THE LANCET.

HEALTH OF GOVERNMENT OFFICIALS IN WEST AFRICA.

THE Colonial Office, in a report issued on June 14th (obtainable from the Crown Agents for the Colonies, 4, Millbank, London, S.W. 1. Price 6*d*.) draws attention to the continued improvement in the general standard of health among non-native Government officials in West Africa. So far no adverse effects appear to have resulted from the longer tours of service under the new regulations. The number invalided out of the service in 1922 was equivalent to a rate of 20·8 per 1000 as compared with 16·6 in 1921; in spite of this increase, the rate was lower than that for any year prior to 1921, with the exception of 1917, when it was 20·5. On the other hand, the death-rate last year fell to 8·0 per 1000, a decrease by one-third on the rate for 1921, and the lowest on record. The decrease was particularly marked in the Gold Coast, where the rate per 1000 was 10·5 in 1922 as compared with 20·0 in 1921, and in Nigeria, where it was 6·9 as compared with 8·4. The average number of non-native officials in service during 1922 was 3220—viz., 58 in Gambia, 206 in Sierra Leone, 946 in the Gold Coast, and 2010 in Nigeria.

The West African Medical Service forms a separate branch of the Colonial Medical Service, and details as to appointments, leave and passage, private practice, pensions and gratuities, and instruction in tropical medicine, as published periodically by the Colonial Office, appear annually in the Students' Number of THE LANCET.

CHILDREN'S COUNTRY HOLIDAYS FUND.

To the Editor of THE LANCET.

SIR,—As chairman of the London County Council, and on behalf of the children of London, I appeal for support for the Children's Country Holidays Fund. Through the medium of the fund many of our elementary school-children are enabled to benefit both physically and mentally by a fortnight's holiday in the country. It is not necessary to dwell upon the importance of the fund, but I feel that it would be a real danger if, owing to the falling off in the subscriptions, the number of children sent to the country were restricted. For the year 1923, owing to the financial position of the fund, it has been necessary to estimate for about 4000 fewer children than were sent away last year. This is the ground of my appeal, and whilst appreciating the number of calls which must be made upon the generosity of those who support the fund, I feel sure that there need be no children disappointed of their summer holiday if those to whom the objects of the fund commend themselves will assist according to their ability. Donations should be made payable to the Children's Country Holidays Fund, and should be sent to the secretary at 18, Buckingham-street, Strand, W.C. 2.

I am, Sir, yours faithfully,
HENRY C. GOOCH,
June 29th, 1923. Chairman of the London County Council.

PROFESSIONAL AND BUSINESS WOMEN'S HOSPITAL LEAGUE.

THIS friendly society, whose registered office is at 195–197, Edgware-road, London, W. 2, was founded in 1913 to make provision in severe sickness for women who earn their living by professional or business work. By means of contracts with certain hospitals arrangements are made for beds in private wards to be available for members of the League who live near London, provincial members who are unable to come to town for treatment being aided by a money grant. The annual subscription for ordinary members is 5*s*. The League is now in a flourishing condition, having more than doubled its membership during the past year.

It has been found necessary to limit the age of those joining the League as new ordinary members to 55; on the other hand, a class of student members has been constituted. A new feature of the League's activities is an arrangement whereby a firm of surgical instrument makers allows to members of the League a considerable discount off surgical appliances.

PEOPLE'S LEAGUE OF HEALTH.

AT an emergency meeting of the Medical Council of the People's League of Health, held at their headquarters, 12, Stratford-place, W. 1, it was resolved that a letter should be sent to the Council of the British Empire Cancer Campaign welcoming the establishment of that body, and suggesting a meeting of representatives of that council and members of the Medical Council of the People's League of Health, with the object of determining in what way the League could coöperate in the important work, the resolution passed by the council being: "That in view of the prevalence of cancer, the People's League of Health urges that a cancer survey of Great Britain would be advisable." In July, 1920, the subject of an international cancer survey was discussed by the Medical Council of the League. In view of the great financial stringency prevailing at that time consequent upon the war it was then decided that further action should be postponed. It is on an international basis, through the organisations and institutions with which the League is in touch in India, China, Japan, Australia, Italy, France, Belgium, Czecho-Slovakia, and the United States of America, that the People's League of Health is hoping to be of use to the Council of the British Empire Cancer Campaign.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Thursday, July 12th.

DERMATOLOGY: at 5 P.M. (Cases at 4.30 P.M.)
Cases will be shown.

Tuesday, July 17th.

GENERAL MEETING OF FELLOWS: *at 5 P.M.*
Ballot for election to the Fellowship.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.
WEDNESDAY, July 11th.—5.30 P.M., Mr. H. S. Souttar: The Surgery of Intracranial Tumours.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY, July 9th.—10 A.M., Mr. Maingot: Surgical Pathology. 2.30 P.M., Dr. Saunders: Medical Wards. 3 P.M., Mr. Simson: Diseases of Women.
TUESDAY.—10 A.M., Mr. Steadman: Dental Dept. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 3 P.M., Dr. Pernet: Skin Dept.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Bishop Harman: Eye Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
FRIDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 11 A.M., Dr. McDougal: Electrical Dept. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James' Hospital, Ouseley-road, Balham, S.W.
THURSDAY, July 12th.—4.30 P.M.: Dr. R. Worth: Demonstration of Mental Cases at the Springfield Mental Hospital.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Demonstration of Clinical Cases at 3.30 P.M.
MONDAY, July 9th.—Medical: Dr. J. Browning Alexander.
TUESDAY.—(3 P.M.) Surgical: Mr. Howell Evans.
WEDNESDAY.—Eye Cases: Mr. Norman B. B. Fleming.
THURSDAY.—Surgical: Mr. H. W. Carson.
FRIDAY.—Diseases of Children: Dr. C. E. Sundell.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.
WEDNESDAY, July 11th.—4.15 P.M., Dr. W. M. Feldman: The Physiology of the Infant.
FRIDAY.—4.15 P.M., Mr. H. S. Souttar: Intracranial Tumours.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, July 12th.—4 P.M., Dr. Pearson: Indigestion after Infancy.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, July 12th.—5 P.M., Mr. L. C. Rivett: Still-birth.

Post-Graduate Lectures

ON THE

SURGERY OF THE THYROID GLAND.

Delivered at the London Hospital on June 8th and 15th, 1923,

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON, LONDON HOSPITAL.

LECTURE I.*

THERE is hardly one, if indeed there is one, subject in medicine or surgery of which we can say that finality of knowledge has been reached. The inexactitude of our knowledge of the diseases of, or even of the normal condition of, the thyroid is especially noticeable, and the more we study this subject the more we realise how uncertain are our views and how we must be prepared to alter them as fresh evidence arises. It is manifestly impossible to discuss the whole subject in two lectures; I therefore propose to limit my remarks to the various forms of innocent overgrowth of the gland, for to such lesions surgical measures of treatment are most applicable. These overgrowths may for convenience be best classified as follows:—(*a*) Localised: adenomata and fibro-adenomata, cysto-adenomata, and pure cysts; (*b*) Diffuse: colloid goitre, adeno-parenchymatous goitre, and exophthalmic goitre or Graves's disease.

If such rare cysts as hydatids are excluded from the first group it will be found that all these lesions commence as pure adenomata; in the second group the adeno-parenchymatous is simply a combination of colloid goitre and adenomatous masses, although, as I shall show presently, there is a definite tendency for a colloid goitre to develop localised overgrowths. Hence, as Plummer has frequently insisted, there are really only three innocent overgrowths of the thyroid, although various combinations of such overgrowths frequently occur. These primary enlargements are adenomata, colloid goitre, and exophthalmic goitre.

ADENOMATA.

Pathology.

True adenomatous enlargements commence in a thyroid which is previously healthy and are definitely localised and encapsulated. This point must be emphasised because many of the localised overgrowths, especially those seen in endemic goitre and thus found in association with more diffuse changes, have a less well-defined capsule and are, in fact, often not adenomata at all. The true adenomata are frequently single, although not uncommonly two or three may be present. They occur in any part of the gland. In the early stages they form spherical masses of solid glandular tissue which show already a distinct fibrous capsule. They tend steadily to progress in size, but rarely reach the diameter of 1 inch without showing definite evidence of degeneration. The microscopic study of a small adenoma will show that it consists of vesicles lined by epithelium, cuboidal or flattened according to the size of the vesicle. These are much larger than normal, and may be 10 or 20 times the size of the vesicles seen in a healthy gland. In nearly all cases the characteristic feature is the irregularity in the size of the vesicles, many small vesicles being packed between those which are enlarged. As the vesicles increase the walls atrophy and the adjacent cavities run together. It therefore happens that an adenoma 1 inch or more in diameter nearly always shows areas of so-called colloid degeneration—that is to say, there are spaces perhaps only as large as a pea, perhaps 1 inch or more in diameter, which are filled with semi-fluid colloid material. This is the origin of the ordinary cystic degeneration of an adenoma, and in some cases the process may progress so far that the whole of the vesicular walls are destroyed and a pure cyst is left, formed of the original fibroid capsule and filled with fluid colloid material. During the destruction of the vesicular walls capillaries may be ruptured and hæmorrhage may take place into the cavity of the cyst. Hence the fluid is either brown in colour or is formed almost wholly of altered blood. At times the hæmorrhage is severe so that the cyst rapidly increases in size, and on removal is seen to contain a large quantity of blood. In the more chronic cases there is an increase of fibrous tissue in the capsule or in the septa. Such a change may be excessive, so that the adenoma in very large part is formed of fibrous tissue, giving rise to the so-called fibro-adenoma. At other times there are calcareous changes within the fibrous tissue, and it is not at all uncommon in old adenomata to find small areas which grate when the tissue is cut and which consist of a calcareous deposit, or sometimes indeed of true bone. This calcareous change may be so excessive that the whole capsule is converted into a stony membrane which does not collapse when the tumour is incised. Another very important and not infrequent change is the formation of the so-called thyrotoxic or fœtal adenoma. Plummer[24] was the first to direct attention to this condition, although Langhans[15] had previously laid considerable stress upon a condition which he described as proliferating goitre. In such fœtal adenomata a naked eye section will show that the tumour has a much more fleshy or granular appearance. In fact, the cut surface will much more resemble that of an exophthalmic goitre than of a normal thyroid. Microscopically it will be seen that the section is made up of solid masses of cells which are often small and embryonic in type, and if arranged in lobules show a very small amount of stroma between. Bloodgood[2] and Goetsch[10] have both called attention to the fact that in the normal thyroid there are two types of cell. There are those forming acini with a more or less definite basement membrane and certain interstitial epithelial cells which lie loosely between the acini. Meleney[23] has shown that it is these interstitial cells especially which are so increased in the formation of the fœtal adenomata. The importance of this change lies in the effects of such cellular overgrowth. McCarrison[16] regards these cells as reserve parenchymatous cells from which new acini are formed as required. In their more embryonic state they may, when they proliferate, not only give rise to hyperthyroidism, but may, indeed, closely resemble in appearance a carcinomatous change. The difficulty in making a differential diagnosis is increased by the fact that not infrequently this variety of tumour does in fact become true carcinoma. Speese and Brown[25] investigated a series of 28 cases of malignant disease and found that 19 of these arose in previous adenomata and that the average time that elapsed before the adenoma showed malignant changes was $12\frac{6}{10}$ years. It was interesting to note also that in five of these cases of carcinomata toxic manifestations of the adenoma were present before there was definite malignant change. Wilson[27] believes that practically all malignant tumours arise from this variety of fœtal adenomata. In a later communication he[28] investigated the complete literature of this subject and found that there were 193 malignant tumours in a series of 74,335 collected necropsies. Of 97 cases in the Mayo Clinic 50 were only diagnosed by pathological section after removal. Of a further 290 cases in the same clinic only 61 had not noticed a previous thyroid enlargement. He says that if the enlargements are due to circumscribed proliferation of the parenchymatous tissue they are adenomata. If they remain encapsulated and slowly degenerate they are benign. If they are associated with symptoms of slowly developing hypermetabolism with cardiac disturbances they are toxic non-exophthalmic goitre, the toxic adenomata of Plummer. If they continue to proliferate they penetrate their capsule, invade and metastasise, and are then malignant. He points out that histologically it may be almost impossible to differentiate the fœtal adenomata from the carcinoma. He therefore lays down the dictum that any sizable adenoma composed of embryonal tissue, if in a patient of cancer age, is potentially malignant although still contained entirely within the capsule.

---

* Lecture II. will appear in a forthcoming issue of THE LANCET.

Ætiology.

Although histologically these tumours appear to be simple adenomata they manifestly differ very considerably in many particulars from adenomata elsewhere. They frequently occur in association with endemic and colloid goitre. As will be shown later they very often have a definite function and may give rise to hyperthyroidism. They also react very considerably with the needs of the body tissue, and thus are often found enlarged during pregnancy and menstruation. The single localised adenomata may possibly be due to the same factors that give rise to more general enlargements, but the evidence on this point is much less clear. There is, however, a very distinct family history. In my own series of 155 operated cases there were 21 in whom other members of the family, usually sisters or brothers, were affected. In such cases there was usually more than one other affected member in the family, and thus it is possible, just as with the endemic and colloid goitres, that this is not an hereditary fault but that all the children and perhaps the parents are exposed to the same faults, whether they be toxic or dietetic. The researches of Kocher and McCarrison seem to show that single localised adenomata are relatively rare in the endemic areas. As with all other varieties of thyroid enlargement the female sex is much more frequently affected than the male. In my own series there were 14 males and 141 females. The age of onset is somewhat later than that of the colloid goitres, and in my own series many first noticed the tumour between the ages of 30–40. Like the colloid condition, however, the change is often first noticed at puberty.

Symptoms.

A small, localised mass occurring in one lobe of the thyroid may be present for many years, and beyond causing the patient a certain amount of annoyance from its unsightly appearance may give rise to no symptoms. Very often, however, a patient who is afflicted, even with a relatively small adenoma, will complain of a considerable amount of pain and discomfort. The majority seek advice chiefly on account of the increasing deformity. In my own series this symptom was complained of in nearly every case, but it was the sole complaint in 30 cases only. When the tumour has reached a considerable size the deformity may be very great, and when it is sufficiently large to attract the notice of the patient's friends may cause considerable annoyance. If pain alone is complained of, it would seem often to be more imaginary than real. The patient will state that there is a pricking sensation in the throat and that there is pain in swallowing. At other times she will complain of pain commencing in the tumour itself, radiating widely up the neck and passing to the head. Only on rare occasions is it noticed, when other symptoms are absent, that there is a feeling of localised heaviness and pressure. If there is a sudden increase in size from the presence of a hæmorrhage, the pain may be considerably increased.

The most important symptom, and the one which most frequently demands intervention, is that of pressure upon the surrounding structures, especially upon the trachea. When the tumour has reached a certain size there is always some dyspnœa; this symptom determines the necessity of operative interference. In some cases it may be very slight or only present upon exertion, so that if the patient is able to lead an easy and comfortable existence it will cause little disability. When the adenoma is placed posteriorly, or if there be two adenomata, one in each lobe, the pressure and resulting deformity is likely to be more marked and the dyspnœa will then be increased. In some cases, indeed, it may have progressed so far before treatment is sought that the patient may have difficulty in sleeping, and may have to lie in bed with her head and shoulders well propped up. If there has been any sudden increase in size, either from hæmorrhage or from some inflammatory change, the dyspnœa will be rapidly increased and may become a serious and dangerous symptom. The condition is much more marked if an adenoma in the lower part of the thyroid has grown downward and become fixed within the thoracic entry. Such a condition, which is usually described as a retro-sternal goitre, is relatively rare. In Berry's[1] series of 500 cases it was only present in 22. Under such conditions the dyspnœa may be most alarming. During expiration the mass may be forced up in the neck and the air may escape with comparative ease, but during inspiration it is drawn down, the trachea is further obstructed, and there is great difficulty in the air entering the lungs. It is well to remember that dyspnœa with a thyroid adenoma may not be due to the visible tumour. A patient may have a prominent adenoma in front of the thyroid and yet the dyspnœa may be entirely due to a second adenoma seated more posteriorly or to an intrathoracic growth which is barely visible. Some of these retrosternal goitres may, indeed, on an ordinary examination, be entirely overlooked, although as a rule they will be pushed up into the neck during forced expiration, such as occurs on coughing. Some, however, may be only diagnosable after an X ray examination of the upper portion of the thorax. Fortunately, these large and more fixed growths have not uncommonly undergone a calcareous change, so that they will give a well-defined shadow on an X ray examination. Other pressure symptoms are relatively uncommon. Now and again patients will complain of difficulty in swallowing, but such a symptom is rare. Occasionally a simple adenoma may be accompanied with alterations in the voice from pressure upon the recurrent laryngeal nerve. It is well to remember this, for it used to be believed that the presence of such symptoms was a clear indication of carcinomatous changes.

Adenomata of long standing are not uncommonly associated with some evidence of hyperthyroidism. Special stress has been laid upon this change, for it has often been claimed that the good results of the surgical treatment of exophthalmic goitre are due to the inclusion of a large number of these cases which can be operated upon with practically no risk. Plummer[24] was the first to clearly differentiate between these two conditions. As a rule the changes do not develop until the adenoma has been in existence for many years. Judd[12] found that in a series of 100 cases the toxic symptoms only developed after an average period of $19\frac{4}{12}$ years, and in Sistrunk's[25] series only after an average period of 16 years. Haggard and Dunklin[11] found that a large number of their cases developed such symptoms, but they were usually only present in patients between the ages of 35 and 40. They also laid stress upon the fact that such symptoms were very likely to be induced by the administration of iodine, which is so often given to elderly women with long-standing goitre. Although in these cases there is a very definite evidence of hyperthyroidism, this is, as a rule, incomplete. The cardiovascular system is usually more affected, the pulse is increased in rapidity, and later is often irregular; there is evidence of cardiac dilatation, and auricular fibrillation may be present. Although there may be a small amount of tremor the nervous system is always affected to a less degree than in true Graves's disease. It is occasionally stated that there may be some degree of exophthalmos, but in my own series I have never been able to find any true eye changes with a toxic adenoma. It must be remembered here that a patient who has true Graves's disease—that is, a cellular proliferation of the whole of the thyroid gland—may also have an adenoma. In such a case, which must be sharply distinguished from a toxic adenoma, the characteristic nervous and ocular symptoms of true Graves's disease will be present. In these cases of fœtal adenomata the basal metabolic rate is never increased to the same degree as with true Graves's disease. Haggard and Dunklin[11] found, for instance, that in their series it was raised by about 35 per cent., as compared with a 66 per cent. average increase in Graves's disease. Moreover, after operation it rapidly falls, so that it is only increased by 7 per cent. within two weeks of operation. In the later stages there will not infrequently be evidence of renal degeneration.

Treatment.

If these adenomata of the thyroid gland were ætiologically comparable with adenomata elsewhere, an operation would be indicated in them all, for being true tumours no other treatment would be available: they would steadily increase in size, there would be the danger of sudden enlargement and dyspnœa, and of the onset of malignancy. It has been my aim, however, to show that in many ways these tumours differ from true adenomata, and hence the general surgical rules are not applicable. I would regard as indications for operative interference:—

1. *Failure to Obtain Relief by Medical Measures.*—If, when first seen, the tumour is associated with a diffuse enlargement, medical treatment should always be tried. It may happen that the adenomatous mass will entirely disappear, but even in the more unsatisfactory cases the general enlargement will lessen and the size and shape of the adenomata will become better defined. It is my custom also in all cases in which the adenoma is soft and ill-defined to try a course of medical treatment. In such cases the mass is less likely to be a true tumour, and not uncommonly very considerable improvement, if indeed not a complete cure, may be obtained by such measures. If, however, the tumour is very hard and sharply defined, which usually means that there is either some degenerative change in the wall of the adenoma or that it has been converted into a cyst, then, manifestly, no medical measures will bring about a cure.

2. *A Steady Increase in Size with Resulting Deformity.*—If these tumours are very small, and give rise to no disability, no operation need be undertaken, but in such cases a careful watch should be kept upon the patient, and this is more especially so if she is over the age of 30. In fact, if a tumour has been in existence for many years, and the patient is 35 years or more, an operation should be advocated, especially if there be the slightest evidence of any toxic symptoms, for it is these cases that are so likely to become malignant in later years. If the tumour is so large that it causes a definite deformity, operation is clearly indicated. There is, perhaps, one exception to this statement, and that is if the patient be pregnant. Unless there be very urgent dyspnœa, no operation should ever be *undertaken* for a goitre during pregnancy. It is astonishing to what an extent an enormous goitre seen in the later months of pregnancy may diminish in size within a month or two after the confinement or after the completion of lactation.

3. *The Presence of Dyspnœa.*—This is the chief and most important indication for operative interference, and even if it does not greatly interfere with the patient's life it is evident that pressure is being caused and that the tumour is enlarging. Should difficulty in breathing be so marked, or should the patient's employment be such that her work is seriously interfered with, the necessity for operation will be much more urgent. If the disease has been allowed to progress so far that the patient cannot sleep on lying down, the operation should be undertaken as soon as possible, for at any time an attack of severe dyspnœa may occur, and if it takes place at night it may give rise to a fatal result before help can be obtained. Acute temporary attacks of suffocating dyspnœa are probably due to hæmorrhages and are a clear indication of the urgent need of operative treatment. The presence of a retro-sternal goitre causing dyspnœa will call for interference as soon as possible, for the longer the condition is left the greater the danger and the more difficult the operation.

4. *Other Pressure Symptoms.*—Evidence of pressure upon the recurrent laryngeal nerve, blood-vessels, or œsophagus is usually evidence of the rapid increase in size of the adenoma, and is therefore an indication for removal.

5. *Presence of Pain.*—A complaint of pain without other symptoms is rare, but sometimes it may be an indication of early carcinomatous changes, and in any case, if it be sufficient to cause the patient discomfort, operation should be undertaken at an early date.

6. *Presence of Hyper-Thyroidism.*—Not only are toxic changes a considerable danger to the patient, but, as has already been pointed out, such cases are more likely to undergo carcinomatous change. An operation should therefore be strongly urged. It is remarkable to what an extent the grave discomfort which is caused by the toxæmia will improve by operative treatment. Unless degenerative changes have already been set up in the heart and kidneys the whole of the symptoms will frequently disappear within two or three weeks of removal of the tumour.

In performing an operation upon an adenoma many precautions will have to be taken. As a routine measure ether will always be the anæsthetic of choice. Chloroform for any goitre operation is a dangerous drug. If there be many toxic symptoms large quantities of fluid and a prolonged rest in bed will often be a valuable preliminary of operation. These measures will, however, be discussed more fully when operations for exophthalmic goitre are considered. If there be pressure symptoms the anæsthesia should be very light. Under such circumstances the intratracheal ether held out great hopes, but it cannot be said to have fulfilled expectations. Crotti[3] has laid stress upon the defects of this measure, which he says has often proved unsuccessful because of the necessity of anæsthetising before passing the tube. Extreme hyper-extension of the head is required and occasionally the tube may fail to pass beyond the obstruction. The operation of choice is that of enucleation of the adenoma. In actual practice, however, this is only carried out with very small adenomata. The larger tumours are so firmly adherent and have so greatly thinned out the front of the thyroid that a wedge of this anterior surface is usually excised and the adenoma then shelled out from the thyroid tissue behind. To this operation Berry has given the name of resection-enucleation, and it is unquestionably the operation of choice, for it removes only the tumour and leaves behind all the normal thyroid tissue. After removal the cavity of the thyroid gland is closed with a running mattress suture which obliterates the cavity and completely controls all hæmorrhage. It is always advisable after such an operation to insert a small tube for 24 or 48 hours. No harm is done by such a measure, and the resulting scar is practically invisible. In certain cases where an adenoma is very large and limited to one lobe the tissue of that lobe may be so destroyed that a hemithyroidectomy may be required, but this is only the case in exceptional circumstances. Where the adenomata are many and are associated with a diffuse enlargement, a modification of the wedge resection—which will be described as the operation for colloid goitre—may be requisite. The greatest technical difficulties are found in operations for a retro-sternal goitre. Fortunately, however, these goitres receive all their blood-supply from above, so that the vessels passing down to the goitre can be all ligatured and divided before the removal is essayed. It is in the delivery of the mass from within the thorax that the greatest difficulty and danger may be encountered, for at such a time pressure upon the trachea is greatly increased.

Results of Operation.

The results of operative treatment on these lines are extremely satisfactory. The danger of operation is almost non-existent, and if it were not for the presence of long-standing hyperthyroidism with its cardiac degeneration, or of severe pressure such as is seen in the retro-sternal goitres, there would be practically no mortality. In my own series there were three deaths in 155 cases, and in all these cardiac changes were advanced. The after-results, too, are extremely satisfactory. Single adenomata practically never recur, but if they are multiple, and especially if there be any diffuse change in the gland, a more guarded prognosis must be given. Not only is the mortality of operation very considerably higher, but the adenomata are more likely to recur, so that now and again cases will be met with in which, a year after operation, the goitre is as large as before.

Colloid Goitre.

The colloid goitre, or, as it often used to be called, the parenchymatous goitre, differs from an adenoma in so far as the change is diffuse and not limited to one small section of the gland. Two types of the disease are described, the endemic and the sporadic, but it is probable that there is no real difference in these two conditions. In certain areas, such as Switzerland and in the Gilgit and Chitral Valleys, the work of Kocher and McCarrison[19] has shown that the disease is so widespread that a very high proportion of the population may be severely affected by the disease. It is probable, however, that in these places the same causative factors are only present to a more marked degree. In England the disease is now widespread, and although it is still the custom to describe areas where it is endemic, it is very doubtful whether a much higher proportion of cases is situated in these areas. The actual frequency in England is difficult to ascertain, as so many cases are of a minor degree which do not require any operative interference. More advanced examples form, however, a very large proportion of the cases attending hospital out-patient departments, so that unquestionably the disease is very widespread. In the endemic areas it is a most serious menace. Oswald of Zurich states that 1900 Swiss recruits are discarded each year for low stature, which is due in part to a cretinoid state, and that there were 50,000 cretins recognisable at sight. McCarrison[16] found that in some Himalayan villages the disease was so common that it was difficult to find a man, woman, or child not suffering from the deformity. In India as a whole, at the time he wrote, there were not less than 5 million persons afflicted with goitre, while ½ million was a low estimate of the numbers who suffered from its congenital manifestations. He also states that in some Himalayan villages as many as 60 per cent. of infants still at the breast have been found to be goitrous.

Pathology.

The essential pathological change as found in young girls in England is a diffuse enlargement of the whole thyroid gland. The normal shape is more or less maintained, the surface is smooth with large vessels running beneath the capsule and shows no nodular enlargement. The increase in size may be very considerable, a lateral lobe not infrequently being 5 in. in length and 3 in. in width and thickness. The gland is much firmer in substance, and on cut section has a characteristic appearance. The surface consists of small globules which are visible to the naked eye, the appearance being somewhat similar to that of a sago pudding. It is yellow-pink in colour and not very vascular. On microscopic section there is an enormous increase of colloid material. The vesicles are dilated to 30 or 40 times their normal diameter and are filled with colloid. The material differs from that of a normal gland in that it is much more readily stained with eosin. The lining membrane of the dilated acini consists either of a single layer of cuboidal cells or of cells which have become flattened from the pressure of the colloid. The inter-acinar cells are seen in clumps between the dilated acini and are not increased in number. In England the pathological changes do not as a rule progress beyond this, but if the condition has been long in existence further changes may take place in one of three directions: (1) Degeneration of the thyroid tissue; (2) formation of localised adenomatous masses; or (3) a diffuse proliferation passing on to Graves's disease.

In the first condition the acinar walls may break down, masses of colloid may collect, or there may be evidence of a chronic inflammatory change passing on to fibrosis and even to hyaline and calcareous degeneration. If these degenerative changes proceed to an extreme degree the patient may become myxœdematous and the thyroid will then decrease in size and may be replaced by a fibrous atrophic mass. In long-standing cases it is not uncommon for rounded or circumscribed masses to develop apart from the main tissue of the thyroid. These are sharply defined and appear to be adenomatous, but they rarely have the same well-defined capsule as is shown by the true adenomata. McCarrison regards them as degenerative masses which arise from the inter-acinar cells and as an attempt on the part of the thyroid to replace that portion which has undergone atrophy. Hence, in the endemic areas large nodular thyroids, which in this country are often described as the adenoparenchymatous type, are common. The adenomatous masses themselves, just like the simple adenomata, will show varying changes. There may be a colloid degeneration with the formation of cystic-like spaces; there may be masses of fibrous or calcareous tissue or there may be a large cellular proliferation giving rise to toxic symptoms just as in the isolated fœtal adenomata. McCarrison[16] has also shown that in the areas where the goitre is endemic repeated periods of hyperplasia occur during succeeding springs, the gland reverting in the interval to the colloid state.

Under certain conditions the epithelium lining the acini will proliferate, the amount of colloid material will diminish, and the whole gland will become much more cellular. The patient will then develop symptoms of hyperthyroidism, and in this country it is not at all uncommon to find cases of true Graves's disease which have commenced as a simple colloid goitre. Wilson[29] and McCarthy[21] have shown quite clearly that there is a very definite relationship between the amount of hyperthyroidism and the degree of cellular proliferation, so that it is possible to accurately foretell the pathological picture from the nature of the clinical symptoms. Curiously enough, in areas where goitre is endemic true Graves's disease is relatively uncommon, and Eggenberger[5] says that in Switzerland at least half of the cases of Graves's disease are attributable to the excessive medical prescription of iodine. McCarrison[16] also has noted that Graves's disease is rare in regions where goitre is endemic, and in the Himalayan valleys he had seen comparatively few cases in ten years, although the disease was not infrequent among the European residents in such localities.

Ætiology.

An hereditary factor in the colloid goitres is even more marked than in the cases of adenomata, and in my own series it was present in 11 out of 41 operated cases. A further interesting fact has also been noted: there have been several cases in which colloid goitre has been associated with deaf-mutism, and under such circumstances those members of the family who were deaf and dumb also showed goitres, the remaining members being free from both disabilities. McCarrison[16] has laid special stress upon this hereditary factor, and he has found that it is especially common among the Syeds, who, being descendants of the Prophet, are permitted to marry only among their own sect. He states that this factor is much more marked in sub-thyroidic persons than others, for in the true goitre it is difficult to tell what is the effect of heredity because exciting causes which produce it in the parent produce it also in the fœtus or the child. The sex influence is a very marked factor, but it is of interest to note that in endemic areas this influence is only noticed after puberty. In quite young children the sexes are equally affected. In this country the majority of colloid goitres appear in young girls at the age of puberty, although the change may persist until long after this age. In my own series 79 per cent. of the cases occurred in women, and in nearly all of these the onset was between the ages of 15 and 20. The close relationship of the enlargement to sexual changes has long been noted. Not only is the condition much more common at the age of puberty, but there is a tendency for an enlargement of the thyroid to occur during menstruation and to a greater degree during pregnancy. This is not uncommonly seen in otherwise normal women, but if they are the subjects of goitre the increase in the size of the gland is much more manifest. It is well known that under such conditions there is not only an increase in the size of the gland but there is a hyperactivity, and thus women who suffer from a mild hypothyroidism are always at their best throughout the course of a pregnancy. Occasionally goitres may be found at birth or even in young children. In this country such a condition is rare. Berry[1] found that in his series of 500 cases the youngest were five girls aged 14. In my own series one patient was aged 13 and three were 14. As has already been pointed out, however, in endemic areas congenital goitres are quite common. Among sporadic cases there is very little definite relationship between the presence of goitre in the parents and cretinism in the children. In the endemic areas this relationship is very constant. It has already been mentioned what a high proportion of the Swiss population are cretinoid, and McCarrison has made some very interesting observations in the endemic areas in India. He has shown that cretinism does not occur until the second or third generation of a goitrous family, and that it appears to be more common in certain families, especially those who are ill-nourished. Consanguinity also plays an important part. Curiously enough, males were more commonly cretinoid than the females, the proportion being 5 of the former to 2 of the latter. This relation is still maintained even among cretins who are goitrous, but it is less marked, the proportion being 5 to 4. Forty-four per cent. of all cretins in these areas are also goitrous, but usually the goitre is acquired subsequently to the onset of symptoms of cretinism. Moreover, cretins are more likely to develop goitre than normal children, 70 per cent. over the age of 10 having also a goitre. The importance of the hereditary influence is shown by the fact that a goitre was present in 96 per cent. of the mothers of cretins.

Cause.

The older views that goitre was in some way associated with the geological formation, in so far as it was more common in mountainous districts, have had to be very considerably modified. It was believed that in these areas the water was impregnated with lime and that an increase of this substance was the causal factor in giving rise to the enlargement of the thyroid. These views have now been definitely shown to be incorrect. Endemic goitre is by no means limited to mountainous districts or to limestone formations, and there are many high areas in which goitre is practically unknown. An investigation of the functions of the thyroid is more likely to give a clue to the cause of the enlargement. It has long been realised that the thyroid secretion contains a large quantity of iodine. In 1914 Kendall was able to isolate the active principle in a crystalline form, and he has also been able to prepare it synthetically. He has shown that this substance, which he calls thyroxin, contains 65 per cent. of iodine. When administered it acts very slowly, so that its action does not commence for many hours, and after it has commenced continues for about three weeks. In 1895 Baumann devised his method of measuring minute quantities of iodine in the thyroid secretion. He was then able to demonstrate that the percentage of iodine contained in goitrous glands was much diminished, although in large goitres the total amount of iodine might be above that of the normal gland. De Quervain[4] has shown that if rats are given thyroid secretion they become hypersensitive to an oxygen deficiency. By this means he was able to work out the activity of the various forms of goitre, and he showed that the colloid goitres contained much less active principle than exophthalmic goitres. Eggenberger[5] has pointed out that the iodine in the air and water speedily decreased in passing from the sea coast to the upland interior, and that near the sea there was ten times as much as in Switzerland. McClendon and Williams have also shown that there is an inverse ratio between the amount of iodine in the surface waters and the distribution of goitre. It has thus come to be generally believed that a colloid goitre is due to a deficiency of iodine in the water and food. Such an explanation alone would not, however, account for the much greater frequency of this disease in women and its exacerbation during periods of sexual activity. The work of McCarrison[17] has done much to throw light upon this discrepancy. He has shown that deficiency in feeding has a very marked effect in producing colloid enlargement. Pigeons fed on an excess of fat had an increase in size of the thyroid which was due to colloid excess with little or no increase of the epithelium. If raw onions were added to their diet there was an increase of the acinar epithelium. If the birds were also fed upon cod-liver oil there was a very complete freedom from the development of a goitre. He sums up all his experimental work by showing: (1) That a thyroid hyperplasia is readily produced by the use of a diet deficient in iodine; (2) iodine in minute doses will prevent and cure goitre when administered at the proper time and season. Nevertheless, a goitre will often arise when there is plenty of iodine in the food. In other words, a sufficiency may become an insufficiency under certain conditions. The adequate absorption and assimilation of iodine is influenced by gastro-intestinal infection, and the needs of the thyroid for iodine are dependent upon many factors. Excess of fats, for instance, will increase these needs, but there are many other factors, such as sex, age, puberty, sexual activity, pregnancy, menstruation, infections, seasons of the year, &c. In other words, the goitre is usually due to an inability of the thyroid to avail itself of the iodine which is present, or the iodine is insufficient for abnormal demands.

The importance of infection in increasing the demands of the thyroid for iodine, or in preventing its proper assimilation, has of late had very considerable stress laid upon it. McCarrison has carried out a great deal of work on these lines, and has proved that in many of the endemic areas goitre is due to an infection in the water-supply. He has been able not only to produce goitre in human subjects and animals experimentally, but also able to cure already existent goitres by overcoming the infection which is present. The work of Farrant[6] is also of very considerable interest from this point of view. He showed that the various forms of infection are associated with definite changes in the thyroid gland, the acute infections giving rise to absorption of colloid with infolding of the epithelium and a cellular increase—that is, to a pathological change similar to that found in exophthalmic goitre. This occurs with a bacterial infection, or may be produced in animals injected with a toxin—that is to say, it is an antitoxin reaction. In the later stages, and in the more chronic infections, the gland involutes. Large spaces filled with colloid are formed, which spaces vary in size as new ones are continually being formed. Later on fibrosis occurs, the vesicles are destroyed, the gland becomes cirrhotic, and areas of hyperplasia or fœtal adenomata may be formed. The relationship between these two pathological changes is of very considerable importance, for it will be seen that a goitre of the colloid type may merge into one in which there is a proliferation of the epithelium with consequent hyperthyroidism—that is to say, a simple goitre may pass into the much more serious condition of Graves's disease. The factor which appears most likely to cause this change is the careless administration of iodine. Kocher[14] long ago recognised this, and issued a warning against the treatment of lesions of the thyroid by means of iodine and thyroid extracts. Although the greater part of the evidence at our command suggests that the above is the chief cause of a colloid enlargement, there are certain facts that throw doubt upon it. It has long been realised by surgeons that in those cases where an operation is indicated for the relief of dyspnœa the removal of a extremely satisfactory. Single adenomata practically never recur, but if they are multiple, and especially if there be any diffuse change in the gland, a more guarded prognosis must be given. Not only is the mortality of operation very considerably higher, but the adenomata are more likely to recur, so that now and again cases will be met with in which, a year after operation, the goitre is as large as before.

Colloid Goitre.

The colloid goitre, or, as it often used to be called, the parenchymatous goitre, differs from an adenoma in so far as the change is diffuse and not limited to one small section of the gland. Two types of the disease are described, the endemic and the sporadic, but it is probable that there is no real difference in these two conditions. In certain areas, such as Switzerland and in the Gilgit and Chitral Valleys, the work of Kocher and McCarrison[19] has shown that the disease is so widespread that a very high proportion of the population may be severely affected by the disease. It is probable, however, that in these places the same causative factors are only present to a more marked degree. In England the disease is now widespread, and although it is still the custom to describe areas where it is endemic, it is very doubtful whether a much higher proportion of cases is situated in these areas. The actual frequency in England is difficult to ascertain, as so many cases are of a minor degree which do not require any operative interference. More advanced examples form, however, a very large proportion of the cases attending hospital out-patient departments, so that unquestionably the disease is very widespread. In the endemic areas it is a most serious menace. Oswald of Zurich states that 1900 Swiss recruits are discarded each year for low stature, which is due in part to a cretinoid state, and that there were 50,000 cretins recognisable at sight. McCarrison[16] found that in some Himalayan villages the disease was so common that it was difficult to find a man, woman, or child not suffering from the deformity. In India as a whole, at the time he wrote, there were not less than 5 million persons afflicted with goitre, while ½ million was a low estimate of the numbers who suffered from its congenital manifestations. He also states that in some Himalayan villages as many as 60 per cent. of infants still at the breast have been found to be goitrous.

Pathology.

The essential pathological change as found in young girls in England is a diffuse enlargement of the whole thyroid gland. The normal shape is more or less maintained, the surface is smooth with large vessels running beneath the capsule and shows no nodular enlargement. The increase in size may be very considerable, a lateral lobe not infrequently being 5 in. in length and 3 in. in width and thickness. The gland is much firmer in substance, and on cut section has a characteristic appearance. The surface consists of small globules which are visible to the naked eye, the appearance being somewhat similar to that of a sago pudding. It is yellow-pink in colour and not very vascular. On microscopic section there is an enormous increase of colloid material. The vesicles are dilated to 30 or 40 times their normal diameter and are filled with colloid. The material differs from that of a normal gland in that it is much more readily stained with eosin. The lining membrane of the dilated acini consists either of a single layer of cuboidal cells or of cells which have become flattened from the pressure of the colloid. The inter-acinar cells are seen in clumps between the dilated acini and are not increased in number. In England the pathological changes do not as a rule progress beyond this, but if the condition has been long in existence further changes may take place in one of three directions: (1) Degeneration of the thyroid tissue; (2) formation of localised adenomatous masses; or (3) a diffuse proliferation passing on to Graves's disease.

In the first condition the acinar walls may break down, masses of colloid may collect, or there may be evidence of a chronic inflammatory change passing on to fibrosis and even to hyaline and calcareous degeneration. If these degenerative changes proceed to an extreme degree the patient may become myxœdematous and the thyroid will then decrease in size and may be replaced by a fibrous atrophic mass. In long-standing cases it is not uncommon for rounded or circumscribed masses to develop apart from the main tissue of the thyroid. These are sharply defined and appear to be adenomatous, but they rarely have the same well-defined capsule as is shown by the true adenomata. McCarrison regards them as degenerative masses which arise from the inter-acinar cells and as an attempt on the part of the thyroid to replace that portion which has undergone atrophy. Hence, in the endemic areas large nodular thyroids, which in this country are often described as the adenoparenchymatous type, are common. The adenomatous masses themselves, just like the simple adenomata, will show varying changes. There may be a colloid degeneration with the formation of cystic-like spaces; there may be masses of fibrous or calcareous tissue or there may be a large cellular proliferation giving rise to toxic symptoms just as in the isolated fœtal adenomata. McCarrison[16] has also shown that in the areas where the goitre is endemic repeated periods of hyperplasia occur during succeeding springs, the gland reverting in the interval to the colloid state.

Under certain conditions the epithelium lining the acini will proliferate, the amount of colloid material will diminish, and the whole gland will become much more cellular. The patient will then develop symptoms of hyperthyroidism, and in this country it is not at all uncommon to find cases of true Graves's disease which have commenced as a simple colloid goitre. Wilson[29] and McCarthy[21] have shown quite clearly that there is a very definite relationship between the amount of hyperthyroidism and the degree of cellular proliferation, so that it is possible to accurately foretell the pathological picture from the nature of the clinical symptoms. Curiously enough, in areas where goitre is endemic true Graves's disease is relatively uncommon, and Eggenberger[5] says that in Switzerland at least half of the cases of Graves's disease are attributable to the excessive medical prescription of iodine. McCarrison[16] also has noted that Graves's disease is rare in regions where goitre is endemic, and in the Himalayan valleys he had seen comparatively few cases in ten years, although the disease was not infrequent among the European residents in such localities.

Ætiology.

An hereditary factor in the colloid goitres is even more marked than in the cases of adenomata, and in my own series it was present in 11 out of 41 operated cases. A further interesting fact has also been noted: there have been several cases in which colloid goitre has been associated with deaf-mutism, and under such circumstances those members of the family who were deaf and dumb also showed goitres, the remaining members being free from both disabilities. McCarrison[16] has laid special stress upon this hereditary factor, and he has found that it is especially common among the Syeds, who, being descendants of the Prophet, are permitted to marry only among their own sect. He states that this factor is much more marked in sub-thyroidic persons than others, for in the true goitre it is difficult to tell what is the effect of heredity because exciting causes which produce it in the parent produce it also in the fœtus or the child. The sex influence is a very marked factor, but it is of interest to note that in endemic areas this influence is only noticed after puberty. In quite young children the sexes are equally affected. In this country the majority of colloid goitres appear in young girls at the age of puberty, although the change may persist until long after this age. In my own series 79 per cent. of the cases occurred in women, and in nearly all of these the onset was between the ages of 15 and 20. The close relationship of the enlargement to sexual changes has long been noted. Not only is the condition much more common at the

I investigated a series of out-patient cases on these lines, and the results were very interesting. Twenty cases were treated with regular doses of the syrup of iodide of iron and 20 with intestinal antiseptics alone. About 50 per cent. of each group were cured. If the two treatments were combined a further 40 per cent. were greatly benefited, thus supporting McCarrison's view that an excess of iodine may be insufficiently absorbed if intestinal sepsis be present. There is no doubt, therefore, that each case must be considered apart, and that the administration of iodine will have to be combined with attention to the diet and the care in eliminating any form of sepsis and especially intestinal sepsis.

There are, however, certain cases in which surgical treatment is indicated, but it must be remembered that this is always exceptional. The first clear indication is the presence of dyspnœa. Even in such circumstances an operation should only be undertaken if the dyspnœa is sufficient to cause discomfort, if it is steadily progressive, and especially if it interferes with the patient's sleep. The second indication is the presence of multiple adenomata. Since these masses are not true adenomata but are secondary to the general change, an operation should not be performed unless medical treatment has been tried. Moreover, such measures must always be continued after the operation or the condition will recur.

The onset of hyperthyroidism, if it is not controlled by medical treatment, is also an indication for operative treatment. The case will then pass from this group into that of Graves's disease, where the indications for operation will be more fully considered. In certain cases where the disease has existed for a long period and has proved refractory to all forms of medical treatment, an operation may be undertaken as a means of overcoming deformity, but it must be remembered that such cases are exceptional.

In cases of the above type where an operation is essential the same preparation and the same precautions in the use of the anæsthetic will be taken as in cases of adenomata. It was formerly the custom to to perform a hemi-thyroidectomy, removing one lobe and half the isthmus. There are, however, several drawbacks to this operation. If the thyroid is very much enlarged removal of one side only may lead to an increase in deformity of the trachea, and thus may not only fail to relieve but may actually increase the dyspnœa. As a general rule a hemi-thyroidectomy is followed by a rapid decrease in the size of the remaining half of the thyroid, but in certain cases the other lobe may not diminish or may even increase in size. Under such circumstances the deformity is considerably exaggerated, for a lateral enlargement is more noticeable than one that is symmetrical. The operation, therefore, of choice is that of a double wedge-resection combined with division of the isthmus. Free access is gained to the thyroid gland by means of a long collar incision. The pre-tracheal muscles are preferably divided and the whole of the thyroid is exposed. The isthmus is divided down to the trachea and dissected free, so that all pressure upon this structure is removed. Each lobe is grasped by the assistant so as to control all hæmorrhage. A wide wedge with its base anterior is excised from each lobe in turn, and the wide gap which is left is sutured together with a running mattress suture of catgut which controls all hæmorrhage and restores the lobe to shape. The reconstructed lobes are then dropped back into position, a small tube is inserted, the muscles are sutured, and the wound is closed. Should there be multiple adenomata the wedge will have to be modified, and after the elliptical incision is made in front of the enlarged lobe the individual adenomata will be shelled out with the wedge instead of making a clean incision. If there be any evidence of hyperthyroidism or manifest toxic changes an operation of the above type may be associated with too much risk. Under these circumstances there will be less danger, less trauma and hæmorrhage, if a partial thyroidectomy be performed. These cases should, in fact, be treated not as simple colloid goitres, but as cases of Graves's disease. The same preparations will be made for operation, and the same technique will be carried out.

Results of Operation.

The results of operation in this type of goitre are not quite as satisfactory as those of adenomata. This is due to the fact that an operation is only carried out in the presence of some complication, whereas with an adenoma removal is often called for when the patient's condition is quite good. In my own series of 42 cases there were two deaths. One of these was due to the fact that the trachea was absolutely flattened and after removal showed a valvular collapse on inspiration. An attempt was made to overcome this by intubation of the trachea, but the patient collapsed rapidly and died a few hours later. In spite of the danger of infection of the wound I believe it would have been better in this case to have performed a subsequent tracheotomy as giving a freer air entry. The other case showed a considerable amount of toxic change and hyperthyroidism, although the changes were not sufficient for the case to be included among those of exophthalmic goitre. The more simple goitres will usually make very good progress after operative treatment, but should there be any adenomatous masses it is always necessary to carry out post-operative medical treatment or the enlargement will recur and obstruction again become manifest.

portion of the thyroid either in the form of a wedge resection or as a hemithyroidectomy is, in the majority of cases, followed by a rapid diminution in the size of the remaining portion of the thyroid. This, together with the pathological appearance, which consists of dilated acini with deeply-standing colloid material, suggests that the disease is not so much one of overgrowth and secretion of the thyroid, but rather of a damming up of its secretion within the thyroid gland. This would also account for the fact that so many of these cases show a hypo- rather than a hyper-thyroidism. Acting on this assumption in one case presenting dyspnœa, I operated by making a simple incision through each lobe. It was of interest to see that the operation was followed by a diminution of the size of the gland, which progressed into a complete cure. The progress was, however, so relatively slow as compared with that of a wedge resection, that it was not considered advisable to repeat it.

Symptoms.

The disease, as a rule, commences in this country as an enlargement of the thyroid gland, which is first noticed in girls at or about the age of puberty. At first it is very difficult to determine whether the enlargement is only physiological or pathological, and a large number of female children at this age show a distinctly enlarged thyroid which disappears within a few weeks or months. In fact, the size of the thyroid is so variable in women that it is often difficult to say what is its normal size. As the condition progresses the enlargement steadily increases, until it forms a noticeable swelling with very distinct characters. The whole gland participates, so that the normal outline is maintained. At this stage the enlargement is soft and ill-defined, so that on palpation it may be difficult to determine its exact outline. There is no visible pulsation of the overlying veins, there is little or no increase in the pulsation of the arteries, no thrill can be felt at the superior pole, and the enlargement is not tender. In such cases a family history is common. Children in this stage are often brought for advice because a small swelling has been noticed, and because the mother has feared trouble owing to the presence of goitre in other members of the family. Later the most important symptom is that of pressure upon the trachea. There will be the onset of dyspnœa of varying degree. At first this will only be found upon exertion, but later it may be present when the subject is at rest, and it may often interfere with sleep. Such patients may have severe suffocating attacks, and even a fatal attack, of acute dyspnœa at any time of day or night. Under such circumstances it will be found that the trachea is much flattened from side to side, so that it shows the well-known scabbard appearance. It is well to remember also that in such cases of extreme pressure there is not only a flattening of the trachea, but also a loss of elasticity from atrophy of the cartilaginous rings. The importance of this change lies in the fact that sometimes removal of the thyroid is insufficient to overcome the dyspnœa; the operation may, in fact, allow the trachea to collapse. Berry has laid stress upon this fact, and has pointed out that a tracheotomy may sometimes be necessary after a partial thyroidectomy. In my own experience this has only been necessary on two occasions. After the partial thyroidectomy the trachea was seen to collapse with every inspiratory movement, so that there was valve-like action with complete obstruction.

Colloid goitres, being as they are uniform in size and enlargement, are not usually associated with retrosternal masses, and hence dyspnœa from obstruction of the thoracic inlet does not occur. Later the nature of the thyroid enlargement may alter considerably, and there may appear in it nodular masses, sometimes very numerous, giving rise to the so-called adenoparenchymatous type. Under such circumstances dyspnœa may occur from a lateral distortion and displacement of the trachea, and there may be pressure upon surrounding tissues similar in nature to that occurring with the adenomata. As a general rule, a simple colloid goitre of this variety shows no symptoms of alteration in thyroid activity, or if any such symptoms are present they are more likely to be of the nature of a hypothyroidism. The relationship between this condition and cretinism occurring in the endemic areas has been mentioned. Sistrunk[26] has shown that with this variety of goitre the basal metabolic rate is either normal or a little below the normal, and this even if there were a certain amount of tachycardia and nervousness. At times, but usually only after a colloid goitre has been in existence for a considerable period, there may be evidence of hyperthyroidism. The general symptoms are, as a rule, the first to show the change. The patient will complain of palpitations and will be found to have a rapid heart-beat. She will become nervous and tremulous, and there may be slight exophthalmos. The thyroid will then be found to be much more vascular, there will be pulsation of the overlying veins, and often a thrill at the apex of the upper lobe. In other words, the condition has passed over to one of true Graves's disease. It is of very great importance to recognise the earliest onset of such a change, for under such conditions the administration of any form of iodine or thyroid preparation will be fraught with considerable danger.

At times very curious intermediate changes are found in long-standing colloid goitres which are difficult to explain either clinically or pathologically. The thyroid may lose its soft ill-defined outline and may become hard and sharply defined. In such conditions it appears to be adherent to the trachea and may be mistaken for a malignant change. The progress of the disease will show, however, that there is little or no change, and I have seen one such interesting case where the condition has been maintained unaltered for a period of over three years. In another such curious case the patient showed a large hard thyroid with evidence of very slight hyperthyroidism. At operation the gland was of almost stony hardness. Pathological reports of the removed portions stated there was a diffuse carcinoma, for the thyroid cells were found widely dispersed in the lymphatics. The gland remained enlarged and hard after the partial removal, but the patient commenced to develop slight evidence of myxœdema. The administration of small doses of iodine was followed by a rapid decrease in size of the thyroid until now it cannot be felt at all and the patient is a typical example of myxœdema who has to be constantly controlled by the administration of thyroid extract. The onset of true malignancy in cases of colloid goitre is extremely rare, and I doubt whether it ever occurs unless the gland has previously been the seat of multiple adenomata.

Treatment.

The treatment of this disease is in itself essentially medical. If taken at the correct period the enlargement can probably always be controlled by medical measures. This is more especially the case in young children and where there is some definite factor such as pregnancy. Under such conditions no operation should ever be considered unless there be the onset of some urgent complication. The treatment usually advised is the administration of iodine or thyroxin, and in the endemic areas it has been advocated that one of the iodides should be mixed in very small doses with common table salt and should in this manner be distributed to the general population, or should be given mixed with chocolate to young children. Such methods of widespread administration have, however, several drawbacks. Attention has already been directed to the fact that in the endemic areas such cases of Graves's disease that occur are usually due to over-administration of iodine, and there is unquestionably a very considerable danger in giving this drug if there is the slightest evidence of hyperthyroidism. Moreover, the work of McCarrison has shown that some other factor is often present, and that the administration of iodine alone may be insufficient.

I investigated a series of out-patient cases on these lines, and the results were very interesting. Twenty cases were treated with regular doses of the syrup of iodide of iron and 20 with intestinal antiseptics alone. About 50 per cent. of each group were cured. If the two treatments were combined a further 40 per cent. were greatly benefited, thus supporting McCarrison's view that an excess of iodine may be insufficiently absorbed if intestinal sepsis be present. There is no doubt, therefore, that each case must be considered apart, and that the administration of iodine will have to be combined with attention to the diet and the care in eliminating any form of sepsis and especially intestinal sepsis.

There are, however, certain cases in which surgical treatment is indicated, but it must be remembered that this is always exceptional. The first clear indication is the presence of dyspnœa. Even in such circumstances an operation should only be undertaken if the dyspnœa is sufficient to cause discomfort, if it is steadily progressive, and especially if it interferes with the patient's sleep. The second indication is the presence of multiple adenomata. Since these masses are not true adenomata but are secondary to the general change, an operation should not be performed unless medical treatment has been tried. Moreover, such measures must always be continued after the operation or the condition will recur.

The onset of hyperthyroidism, if it is not controlled by medical treatment, is also an indication for operative treatment. The case will then pass from this group into that of Graves's disease, where the indications for operation will be more fully considered. In certain cases where the disease has existed for a long period and has proved refractory to all forms of medical treatment, an operation may be undertaken as a means of overcoming deformity, but it must be remembered that such cases are exceptional.

In cases of the above type where an operation is essential the same preparation and the same precautions in the use of the anæsthetic will be taken as in cases of adenomata. It was formerly the custom to to perform a hemi-thyroidectomy, removing one lobe and half the isthmus. There are, however, several drawbacks to this operation. If the thyroid is very much enlarged removal of one side only may lead to an increase in deformity of the trachea, and thus may not only fail to relieve but may actually increase the dyspnœa. As a general rule a hemi-thyroidectomy is followed by a rapid decrease in the size of the remaining half of the thyroid, but in certain cases the other lobe may not diminish or may even increase in size. Under such circumstances the deformity is considerably exaggerated, for a lateral enlargement is more noticeable than one that is symmetrical. The operation, therefore, of choice is that of a double *wedge-resection* combined with division of the isthmus. Free access is *gained* to the thyroid gland by means of a long collar incision. The pre-tracheal muscles are preferably divided and the whole of the thyroid is exposed. The isthmus is divided down to the trachea and dissected free, so that all pressure upon this structure is removed. Each lobe is grasped by the assistant so as to control all hæmorrhage. A wide wedge with its base anterior is excised from each lobe in turn, and the wide gap which is left is sutured together with a running mattress suture of catgut which controls all hæmorrhage and restores the lobe to shape. The reconstructed lobes are then dropped back into position, a small tube is inserted, the muscles are sutured, and the wound is closed. Should there be multiple adenomata the wedge will have to be modified, and after the elliptical incision is made in front of the enlarged lobe the individual adenomata will be shelled out with the wedge instead of making a clean incision. If there be any evidence of hyperthyroidism or manifest toxic changes an operation of the above type may be associated with too much risk. Under these circumstances there will be less danger, less trauma and hæmorrhage, if a partial thyroidectomy be *performed*. These cases should, in fact, be treated not as simple colloid goitres, but as cases of Graves's disease. The same preparations will be made for operation, and the same technique will be carried out.

Results of Operation.

The results of operation in this type of goitre are not quite as satisfactory as those of adenomata. This is due to the fact that an operation is only carried out in the presence of some complication, whereas with an adenoma removal is often called for when the patient's condition is quite good. In my own series of 42 cases there were two deaths. One of these was due to the fact that the trachea was absolutely flattened and after removal showed a valvular collapse on inspiration. An attempt was made to overcome this by intubation of the trachea, but the patient collapsed rapidly and died a few hours later. In spite of the danger of infection of the wound I believe it would have been better in this case to have performed a subsequent tracheotomy as giving a freer air entry. The other case showed a considerable amount of toxic change and hyperthyroidism, although the changes were not sufficient for the case to be included among those of exophthalmic goitre. The more simple goitres will usually make very good progress after operative treatment, but should there be any adenomatous masses it is always necessary to carry out post-operative medical treatment or the enlargement will recur and obstruction again become manifest.

INSURANCE PRACTICE:

A REVIEW WITH CERTAIN CRITICISMS AND CONSTRUCTIVE PROPOSALS.

By A. GARVIE, M.D. GLASG.

THE preparation of this paper suggested itself some weeks ago when the virulent attack was made by a certain medical coroner on panel practice, especially where practitioners were in possession of large panels. Being one who may be classed in that category, I have thought that a brief review might throw some light on a much-abused system. I regret the necessary introduction of personalities.

First it may be pointed out that to a very large extent the routine work of an insurance practice is something new in the annals of medicine. Medical art has more or less in the past been devoted to, if one may use motoring language, the repair of breakdowns; but with the introduction of the Insurance Act, carte blanche was given to any insured person not only to claim the services of his mechanic in a breakdown, but at any time when he thought the car was not in proper tune. There was nothing in the Act to prevent a man claiming Rolls Royce efficiency irrespective of personal abuse or the type of vehicle. Where that could not be obtained, he could grumble about the delinquencies of his mechanic and at the same time suggest that those delinquencies were due to the objectionable system of payment. Further, it is perhaps as well to recall that, previous to the introduction of the Insurance Act, the potentially insured were given to understand that they had merely to report a lack of tune to their medical adviser to draw freely on Insurance funds. As soon as the Act was passed the work of disillusionising them on this point was very promptly and very properly begun; unfortunately, though the politician practised the illusion, the onus of explanation was left to the physician, and too often, when the explanation was not considered satisfactory, the method of payment again came under discussion.

In bringing the work under review real difficulty has been found in fixing some standard on which it could be judged. Obviously, we know next to nothing of what is normal health, or what constitutes a restoration to normal health, for the disappearance of certain disagreeable symptoms does not always mean a status quo ante. On that basis no standard can be fixed. A comparison might be made with the work in private practice, the results in private practice for the time being held out as ideal, but when one comes to realise the number of faith-healing cults, patent-medicine vendors, bone-setters, herbalists, and the whole host of others downwards or upwards to the handy-women with their single box of salve, who had their large clientèle long before the Insurance Act came into force—these, whatever value they may have had, certainly demonstrated that a large number did not find the care of qualified medical men all-sufficient. Comparison is difficult, and more so because failure or transgression in private practice is put down to lack of ability or excusable forgetfulness; under the Insurance Act it is always "the panel." From the fact that the Ministry has asked for a record of the total number of attendances, it would appear that some value is attached to that, but it is the most futile of all standards. It places a premium on eye-service and inefficiency. One consultation of half an hour, where that appears necessary, may be of infinitely more value that 30 of three minutes' duration.

The Standard.

Some standard has been sought within the work itself and the following tests have been applied:—

(*A*) How far (1) loss of patient, (2) permanent disablement, (3) death of patient, may be assigned to (*a*) the system, and responsibility divided between the Ministry and approved societies on the one hand, and (*b*) the art of medicine, and the responsibility divided between the limitations of medical science and personal incapacity or delinquency.

(*B*) How far credit can be given to the system for cure or alleviation of the major illnesses of life acting through the agency of the faculty.

An attempt has been made to present a series of facts in as neutral a spirit as possible and little judgment has been passed, the writer preferring to leave that to others. Where the facts appear personally unfavourable no excuse is offered, for *qui s'excuse s'accuse.* One cannot argue from the particular to the general, but when a series of generalisations are applied to the particular and found wanting, then to a fair mind it suggests the need for revision.

Basis of Review.

Two thousand records of different insurance patients, accumulated during a period of slightly over five years, have been examined. During that time the total number of insured patients on the list has gradually increased to slightly over 2500—the limit fixed in this area—and has been subject to adjustment, a process again necessary. This does not represent the total number who have actually claimed benefit. The work on various occasions has been interrupted through absence and illness, but the interruption has always been to all intents complete; mere triviality of illness has not prevented a record being kept, for anyone caring to investigate primary symptoms will find that trivial illness is an expression very difficult of definition. In Table III. the analysis of disability, where this deficiency from the total actually seen has to be acknowledged, the symbol + has been used to represent a proportionate deficiency from some total figure which can be regarded as a constant, the figures thus retaining a relative value. Where the symbol is absent it may be taken that, as far as it has been possible to ascertain, those are the actual number of cases occurring during the period.

Influx and Efflux of Insured Persons.

There are still 836 persons not indexed since April, 1918, but it is worth noticing that since January, 1920, when a new method of notification was introduced, 845 new patients have been accepted. This would suggest that the total number of persons who have to choose a new doctor in any one year, as compared with the number who might be automatically transferred by change of practitioner, must be relatively large. Those figures could be easily obtained by the Ministry, and would be interesting in view of the injury that the new regulations must sometimes inflict on young men with limited capital seeking to enter general practice.

TABLE I.

Removals from List (304).

Ceased insurance	167*
Left area	81
Transferred by patient's request	33
Transferred at my request chiefly owing to distance ..	23

* 53 have since attended as private patients.

Analysis of Cases Desiring Transfer (33).

Cause not assignable	9
Chronic illness and unable to give relief	5
New address and distance from surgery probable ..	5
Refusal to commit breaches of certification rules ..	3
Opinion resented but still attending rest of family ..	3
Dissatisfied with treatment of private patient—one family	2
Refused to assist admission to local infirmary, one already discharged incurable, the other infectious	2
Pregnancy, and refusal to induce abortion..	1
Four transferences within three years, twice to me ..	1
Objection to locum tenens	1
Transferred by Insurance Committee on charge of negligence	1

Discontent.

Of the 2000 patients, 304 have been removed from this panel. The various causes for the removals have been analysed partly from the notification slips from the Insurance Committee, and partly from notes on the record sheets, and are tabulated (Table I.).

The number of apparently dissatisfied patients appears trifling, even including the nine* for whom no cause can be assigned, but the number is quite large enough in any area to give the impression of a large amount of discontent. It is surprising to observe over what a wide area one individual can noise his grievance. It does not appear to do any real harm. The average working-man has a great deal of sound logic in his make-up and it is very rarely that he allows his opinion of his medical adviser to be biased by the assertions of others. As individuals we ignore it, and perusal of the list will make it obvious that in certain cases one dare not tell the truth even if so disposed. It is doubtful if panel representatives are wise in giving it more than the most casual of notice.

Freedom of Transfer.

Insured persons have always been at liberty to transfer at any moment desired, without questions being asked. Only once has this rule been broken, and that was owing to insolence backed by threats anent certification. The patient was transferred at my request at the first opportunity. Ill-considered resolutions of panel representatives may ultimately rob the average practitioner of opportunities to display any of the time-honoured professional courtesies.

Record Cards of the Ministry.

When the new record cards of the Ministry were introduced their utility was considered, but so far as personal use is concerned they were discarded for the following reasons: (*a*) The space for observations is too small. (*b*) As they are sometimes transferred locally one has to exercise great discretion as to what one commits to paper. They are not privileged, neither is there any penalty for the divulgence of the remarks on them to the patient. (*c*) Records should still be of value even after the death of the individual, and the records of the Ministry are lost to the practitioner. (*d*) The observations of others are of doubtful value, as they may prejudice unfairly one's views of a patient's symptoms.

Certification.

Certification as a cause of needless friction and interference with medical benefit cannot be fully discussed here. Much has been made of the overcrowding of surgeries, and the following figures are worthy of consideration. The average daily number of patients attending surgery while incapacitated was taken over a period of five weeks. The consecutive figures for an average week were, 4·8; 2; 5; 1; 13·8; 2·6. Subordinate officials are not responsible for this state of affairs, neither can practitioners avoid it. Approved societies and the Ministry must share the responsibility between them. It is not purely a local phenomenon. The whole question of certification should be brought under review by the General Medical Council before support is lent to the complaint of Government departments in regard to the laxity of certification. It is surely possible to devise some form of certificate the signing of which would be compatible with self-respect.

Disability.

To analyse the value of the work Table III. has been drawn up to demonstrate (1) the nature of the disability; (2) operative interference; (3) permanent disablement; (4) death. An analysis of the causes of death in the various age-groups is given in Table II. The causes operating to produce disabilities have received much consideration especially in regard to "responsibility," whether it rests with the individual or to some factors quite beyond his control. In the study of preventive measures it is impossible to ignore this. As one's experience grows so does the impression grow that the accidental has as little relationship to the development of disease as the miraculous has to its cure.

TABLE II.

Analysis of causes of death in age-groups.	Age.						Total.
	16–25.	26–35.	36–45.	46–55.	56–65.	66 +	
Old age (over 70)	—	—	—	—	—	10	10

Insular sclerosis	—	1	—	—	—	—	1
Tetanus	—	—	—	1*	—	—	1
Huntingdon's chorea	—	—	—	1‡	—	—	1
Total	4	4	4	13	17	19	61

* Died in hospital. † Certified by deputy.
‡ Post-mortem obtained.

In addition, 10 died of influenza during the epidemic, 1918–19. (Vide Brit. Med. Jour., 1919, ii., 519.)

For the purposes of this paper the disabilities have been divided into various types, more or less arbitrary; they suggest that the inter-relationship of those types and the relationship to the history of disease would form an interesting study. Unfortunately, its study is surrounded with many difficulties; a method to overcome some of these difficulties has been devised, but has not been in operation sufficiently long to prove its worth.

TABLE III.

Analysis of disabilities.	Total.	Operations.	Permanent disablement.	Deaths.

Huntingdon's chorea	1	—	—	1

* All influenzal.

It is necessary to explain that where a similar illness has occurred in a patient, irrespective of the interval between the attacks, it has been given one value. Violence has not been included. The respiratory type is abnormally inflated owing to the epidemic of influenza which occurred during the period under review. The number was not definitely ascertained; a rough estimate places it over 400.

Glycosuria.—These do not include some cases of very transient glycosuria. Routine analysis of urine is carried out and Fehling tested to excess. Of the two, one is known to have had the condition for over ten years and the other two years. Both can be controlled by diet.

---

* The number was originally 11, but since commencing this paper, in two cases favourable opportunities have arisen for inquiry, and in both cases, marriage and removal from this neighbourhood was found to be the explanation.

Operations.—From a popular point of view the most satisfactory feature of the work has been the operative. I have the greatest pleasure in recording this fact, as none of the operations have been carried out personally. Of the 25 alimentary cases, 20 have been for appendicitis with 100 per cent. recovery. All showed evidence of inflammatory trouble. The small number of operations for malignancy is surprising. In one or two cases operation might have been possible if diagnosis could have been made earlier, but in two cases where the condition was very early suspected, the suggestion of laparotomy made them go elsewhere. One, a prominent society official, died under the care of a colleague, and the other again called me in consultation four days preceding death.

Additional Advice.—A considerable number have had the advantage of the opinion of consulting physicians or surgeons, and a large number have on occasion sought the advice of colleagues. Not a few have returned to ask me what I thought about it. One man whose only complaint was pain in the great toe and who died from a sarcoma of the pelvis, consulted "nine doctors and four herbalists" and called to give me the opinion of each. As to the more extensive utilisation of specialists, I have found no difficulty in obtaining their opinions as the need arose—through charitable institutions, or through private consultation where the patient could obviously afford it. Too easy access might tend to lower rather than raise the standard of work, and could easily be carried to absurdity.

Improvement of the Service.—Perhaps the ideal system of treatment would be large individual units where a practitioner could be in the financial position to pay for specialised assistants. For obvious reasons this is not a course likely to be favoured by the Government or approved societies. Their desire to increase the number of practitioners in an area and diminish their individual financial resources is sound tactics, and as politics go, one can overlook the assertion that it has anything to do with the question of efficiency or the advancement of medical science. It is more likely to retard it, so that as an alternative the following suggestions are made.

Diagnostic Centres.

Some method should be devised to bring the work of the consulting room into as close a relationship with physiological and biochemical laboratories as exists at the present time between the wards of a general hospital and the pathological department. It is doubtful whether when we fail to attach a name to a particular disability we are dealing with some unnamed disease. It is more probable that we are really dealing with those processes in a history of illnesses which is usually slurred over as ætiology. It is true that under the present method of certification we have to attach a name to those processes, and one can agree with Rowand of St. Andrews, that to do so is demoralising. We can gather the symptomatology of those cases, but the explanation will, I think, in many cases, be found in the laboratory.

While some of us may feel that we are doing better work by spending some portion of each day in the laboratory rather than running up an indefinite number of visits and consultations, we can never hope to be as proficient as the specialised laboratory worker. On the other hand, it must be rare to find a laboratory worker as skilled in the elicitation of symptoms as a skilled practitioner. There is, therefore, a great need for coöperation between the two. One would suggest that diagnostic centres should be opened up where a patient could be admitted for a few days and during that time remain in touch with his practitioner. This would get rid of the odium attached to the suggestion that one was too lazy to diagnose one's own cases. One cannot see the work going on in clinical laboratories without appreciating how much it is required. Its value has still to be proved, and even if proved, it may mean a new race of practitioners before it will come into its own. But a beginning could surely be made on a small scale as an adjunct to teaching centres.

A Department for Medical Research.

Under the Act there has been established a council for medical research, but the suggestion put forward is for the establishment of a department directly interested in the research work carried out in general practice. It may be urged that the amount of such work is now small. That may be true, but it certainly lacks both assistance and encouragement. It is not good that the ambitious young student should feel that by entering insurance practice he is entering an inferior service with a dead end, and a council of men of mature experience and wide sympathies is much required to assist young graduates during those years when the desire for research is strongest. "Much," said Dr. Johnson, "may be made of a Scotchman, if he be caught young," and the same might apply to the general practitioner. The department could become a great reservoir of knowledge, giving advice when asked, and supplying information when desired.

Much that requires investigation will mean research and observation over a life-time, and unfinished work, without such a department, is likely to be lost. While such work might prove of value to those who follow after, yet it might not be considered worthy of publication in the limited space of medical journals. Even that which has been on wrong lines might save some future worker from a similar error. All this must be voluntary, but the resources of the department should be open to anyone wishing to utilise them. The names should not be known to any local committee. The compulsory keeping of records might be abolished; the value of such records must be very slight, and the labour and finance saved might be applied to the purposes of this department.

Halifax.

THE CAUSE OF DEATH IN INTESTINAL OBSTRUCTION.[*]

By SETON PRINGLE, F.R.C.S. Irel.,
SURGEON TO THE ROYAL CITY OF DUBLIN HOSPITAL.

The cause of death in intestinal obstruction is still a subject for debate, and is a problem which has been constantly before my mind during the past 20 years, each year calling out with greater urgency for solution. Three theories have been advanced: (1) Infection—i.e., escape of organisms through the wall of the obstructed intestine, causing peritonitis; (2) absorption of toxins from the obstructed intestine; (3) depletion of systemic circulation and cerebral anæmia. I have frequently asked myself whether one of these three was the correct explanation, or whether each contained part of the truth?

Toxæmia the Most Constant Factor.

As experience increased with years, I found that the infective theory would only account for a very small proportion of the deaths, most cases dying long before there was marked peritonitis, and I gradually came to look on toxæmia as being the most constant—and probably the causal—factor, but many points still remained at issue. For instance, I found it impossible to reconcile with the toxæmic theory the fact of the sometimes rapid death in strangulation where, presumably, the absorption from the strangulated loop cannot be great on account of the obstructed venous return. Can the toxæmia in these cases arise from absorption from the intestine above the strangulated loop—intestine which was in a condition of simple obstruction? Does the factor of shock and reflex dilatation of the portal system occur in these strangulation cases, thus accounting for the greater rapidity of death? Again, is death in peritonitis due to septic absorption, or is it not often chiefly due to the absorption of toxins from the paralysed and distended gut? In the absence of time and facilities for experimental work, I recently turned to the very extensive literature on the subject, and I think a résumé of the results may perhaps interest other surgeons.

---

[*] Read before the Surgical Section of the Royal Academy of Medicine in Ireland on March 9th, 1923.

I found that a tremendous amount of work had been done, chiefly in America and on the Continent, and that, as a result of all this work, two facts stand out clearly and confirm our clinical experience: (1) Peritonitis is not the chief factor in causing death, which often occurs before its onset and almost always before it is extensive; (2) the higher up the obstruction, the more rapidly is it fatal. For example:

Dogs[1]	obstructed in the rectum live..	28 days.
,,	,, ,, ileo-cæcal valve live	14 ,,
,,	,, 35 cm. below pylorus live	7 ,,
,,	,, 2nd stage duodenum live .	2 ,,
Rabbits[1]	obstructed in colon live	10 ,,
,,	,, in lower ileum live ..	4–5 ,,
,,	,, at end of duodenum live	17 hours.

As regards the other results obtained, the weight of evidence is all in favour of death being due to a toxæmia resulting from absorption of a toxin, or toxins, from the obstructed intestine, and the efforts of most workers have been directed towards discovering the site of production, the nature and the source of the toxin.

Site of Production of the Toxin.

The fact being established that the higher up in the small intestine the obstruction occurs, the more rapid is death, the attention of most observers was focused on the duodenum. It has been shown that if the second stage of the duodenum be obstructed,[3] or if a loop of the duodenum be isolated, closed at both ends and its blood-supply left intact,[4] death occurs in a very few days with the symptoms of toxæmia—i.e., dullness and apathy, tachycardia, muscular weakness and tremors, renal suppression, vomiting, temperature disturbances, and fall of blood pressure; whereas a similar isolation of a loop of ileum is compatible with life for many weeks, death occurring not from toxæmia, but from rupture of the loop and peritonitis.[5 6] If, however, the loop above the obstruction be drained externally or into the intestine,[3 7] or if the loop be kept washed out, the animal survives for a much longer period.[8] Again, if the contents of an isolated duodenal loop be heated to 60° C. for an hour, filtered, and then injected either intravenously or intraperitoneally, rapid death with the same symptoms ensues,[4] and, moreover, dogs can be immunised against this toxin by the injection of gradually increasing doses.[9] Again, if the duodenum with the bile and pancreatic ducts be transplanted so that it drains into the ileum, and then some weeks later the jejunum be obstructed high up, dogs will survive for more than twice as long as dogs in which the duodenum has not been transplanted before obstruction is produced.[1]

These results go to prove that the duodenum and its appendages, the liver and *pancreas, not* only produce the toxin which causes death with symptoms similar to those of intestinal obstruction, but produce it in far greater quantities than any other part of the intestine.

Nature of the Toxin.

The nature of the toxin has not been definitely settled. It is, however, generally accepted that it belongs to *one* of the groups of poisonous chemical substances produced by the disintegration of protein—e.g., proteoses, amines, neurines, and cholines. Several groups of observers have been able to isolate a proteose in an almost chemically pure state from the contents of obstructed duodenal loops.[10 4 9 1] An injection of this proteose produced rapid death with the train of toxic symptoms already enumerated. The probability, however, seems to be that a whole series of the end-products of protein are present in the obstructed intestine, and are active in producing death.[11]

Source of the Toxin.

In considering the possible source of the toxin three different possibilities have to be considered: (1) food; (2) duodenal secretion, either alone or with the bile and pancreatic juice; and (3) products of bacterial action on the intestinal content. Before discussion of the points for and against each of these possible sources, it may be stated that experimental work has so far failed to demonstrate clearly the origin of the toxin. It is generally accepted that it is not derived from the protein of the food, for it has developed both in a loop above a simple duodenal obstruction produced in dogs that have fasted for many hours,[3] and in an isolated duodenal loop which has been carefully washed out before being closed off.[4] As against bacterial origin for the toxin, many points can be urged—e.g., the higher up the obstruction, the more rapid is death, yet the less is the bacterial content. And, again, the isolation of a duodenal loop which contains few, if any, bacteria, is rapidly fatal, whereas the isolation of a loop of ileum, or even of colon,[12] with their numerous organisms, is not incompatible with life for a long period. Many workers, however, [13 14 15 16] cling to the bacterial origin of the toxin, and advance many arguments in its favour—e.g., it has been shown that the fresh secretion of the normal duodenum from which food is excluded is non-toxic, and remains non-toxic if kept under conditions which inhibit bacterial growth, but if it is incubated with its own bacterial content, a toxin rapidly develops, injection of which causes symptoms like those following the injection of the fluid from obstructed loops.[11]

Others—especially Draper, who has operated on many hundreds of dogs—maintain that the toxic substance is a normal secretion of the duodenum and its appendages, the liver and pancreas; that normally it is detoxicated or neutralised by the jejunal and ileal mucosa lower down, but that in obstruction this is prevented, and that, instead, it is retained in the duodenum, is absorbed, and produces the typical toxæmia. In confirmation of this he showed that when dogs with duodenal obstruction are fed with the mucosa of jejunum or ileum from normal dogs, the obstructed animal survived for twice as long.[17] Others have demonstrated that the toxic contents of obstructed loops which cause rapid death on intravenous or intraperitoneal injection, produce no deleterious effects on injection into the intestine of normal dogs.[18] He therefore believes the toxin to be biochemical in nature, similar to prosecretin.

Subsidiary Factors.

In discussing the nature of the toxin it is of interest to note the close resemblance between the symptoms of acute pancreatitis and those of high intestinal obstruction, especially as it has been shown by the following experiment that the presence of pancreatic secretion in the duodenum is necessary for the production of the toxin. (1) If the duct of the pancreas be tied, and then some weeks later high duodenal obstruction be produced, the dog will live about twice as long as when the pancreatic secretion is reaching the duodenum, and that under these conditions a choline—not a proteose—is found in the loop.[7] (2) Obstruction immediately above the pancreatic duct is much less rapidly fatal than obstruction immediately below.[6] As regards the rôle of the bile, Draper showed that the rapidity of death from duodenal obstruction was *not* influenced by the presence or absence of bile.[8]

While, as already stated, the toxæmic theory of death is generally accepted, yet there are not wanting those [22 2 19] who hold the third theory I mentioned—namely, depletion of the systemic circulation, dehydration of the tissues, and cerebral anæmia brought about by (*a*) shock, producing reflex paresis of the splanchnic area with engorgement of the portal system; (*b*) hypersecretion of fluid into the intestine, and (*c*) vomiting. These three phenomena certainly occur, but I think that the first—i.e., shock—is the only one which is a real though variable factor in the production of death, and that the other two are a direct result of the presence of poisonous substances in the intestinal tract and circulation. The supporters of the theory point to the markedly beneficial result of the introduction into the systemic circulation of large quantities of saline, but, taking all the available facts into consideration, I believe this beneficial result can be better explained by considering that the saline acts, chiefly at least, by diluting the toxin in the circulating blood. It has been shown[17] experimentally that injection of pilocarpine for four days, fasting for seven days, or duodenal obstruction for three days, each produces a relatively equal reduction of the quantity of water in the tissues, and yet no serious toxæmic symptoms follow either the pilocarpine injection or the fasting, whereas duodenal obstruction causes death as described above in three days. The only experimental work done on this subject in the British Isles of which I can find a record is that of Wilkie, of Edinburgh.[2] He concludes that the chief factor in producing death is dehydration of the tissues, and he bases this conclusion on the fact that, working chiefly on cats, he was unable to produce death by injecting the contents of obstructed loops into other cats. Another observer[20] has, however, found that although cats develop in obstructed loops toxic bodies similar or identical with those already described, yet they seem to be immune to injection of these bodies, though injection of the same toxic bodies obtained from cats is rapidly fatal to dogs with characteristic symptoms.

Conclusions.

I think we are justified in drawing the following conclusions from all this experimental work:—

(1) The principal factor in causing death in intestinal obstruction is a toxin which is developed chiefly in duodenum, and, although not absorbed from normal intestine, is absorbed under the conditions which prevail in obstruction.

(2) The exact chemical composition of the toxin is still under dispute, but it is almost certainly of the nature of one or other of the toxic bodies derived from protein disintegration.

(3) The exact mode of production of the toxin is also undecided, but probably the presence of pancreatic secretion, and, in a lesser degree, the activities of bacteria are necessary for its production.

(4) While the duodenum is the site of maximum toxicity in obstruction, yet the poisonous substances are developed lower down in the intestine, and it is probable that in the production of these toxins bacterial action plays an important rôle—a rôle which increases in importance the lower down the obstruction occurs.

The value of all this work and the conclusions drawn from it must finally be decided by clinical results. Do the above conclusions hold true if examined in the light of clinical experience? I believe that, for the most part, they do. In the first place, the great majority of surgeons, as the result of clinical experience and quite apart from any experimental work, are agreed that toxæmia is the chief cause of death in intestinal obstruction. Again, all are agreed as to the great benefit of large saline infusions in obstruction cases—a benefit which can be better explained by the toxæmic than by the systemic dehydration theory. Still more strongly in favour of the toxæmia theory is the fact that stomach lavage, useful as it is in all obstruction cases, is most useful in acute dilatation of the stomach. Post mortem, in most fatal cases of this condition, the duodenum is also distended, so that the functional obstruction, whatever its cause, almost exactly reproduces the conditions of many of the experiments on which the toxæmic theory is based, and the benefit of lavage may therefore be explained by the removal of the toxins generated. The same remarks apply to the well-known good results following lavage in those cases, sometimes following gastroenterostomy, where there appears to be a temporary obstruction (probably functional and due to trauma at the operation) to the on-flow of the gastric and duodenal contents.

However, although I believe that toxæmia is generally the chief factor in causing death, yet I think it is rarely—if ever—the only factor. Nor does this theory explain the phenomena of many obstruction cases, for instance, in the cases of rapid death, which sometimes follow acute strangulation, the toxæmia can only be of minor importance. In strangulation we have two distinct conditions: a closed loop from which the circulation is cut off, and, above that, a part of the intestine in a condition of simple obstruction. Toxins, if formed in the closed strangulated loop, cannot be freely absorbed, while death occurs in some of these cases long before there is time for any great amount of toxin to be developed in the simply obstructed intestine above the strangulated portion. Such deaths must be due to shock. Again, it has been a common experience of mine to find on closely questioning the patients in ordinary cases of strangulated hernia that he or she vomited coincidently with the onset of pain, and then perhaps six or eight hours elapsed before any more vomiting occurred. I believe the early vomiting to be due to the temporary shock, and the later to toxæmia. For these clinical reasons, therefore, I think that shock is a more important factor in causing death than the experimental work leads one to believe, and that in some cases of strangulation it is the chief factor, producing, among other conditions, an engorgement of the portal system.

Finally, I would like to suggest that intestinal toxæmia has a large share in causing death in acute septic peritonitis. I have long believed that the fatal result is not due in most of these cases to the absorption of the products of the suppurative inflammation of the peritoneum—the symptoms preceding death are generally those of intestinal obstruction, not sepsis. To my mind, there are three factors at work in acute peritonitis: (1) shock, (2) septic absorption from the peritoneum, and (3) toxæmia from the intestine, the involved part of which is generally in a condition of paresis, producing obstruction. These three factors must be constantly increasing as the inflammation spreads. I would argue that, if the shock and toxæmia be combated, there is a possibility of prolonging the patient's life sufficiently to give the wonderful fighting powers of the peritoneum a chance of dealing with the infection. I believe that I have saved what appeared to be quite hopeless cases by not only using morphia and saline-glucose infusions to combat the shock and toxæmia, but also by directly attacking the source of the toxin by means of an enterostomy high up in the small intestine. The operation I have performed is after the manner of a Witzel's gastrostomy—a No. 12 soft rubber catheter is inserted into the lumen of the intestine through a small puncture and fixed in position by a single catgut stitch, the next couple of inches are buried in the intestinal wall by a continuous in-folding stitch, and the proximal end is passed through a hole in the omentum, as described by Mayo,[21] before being brought out through the abdominal wall. To the end of the catheter a long tube is attached to drain into a bottle beside the bed. An enterostomy after this fashion allows free escape of the toxic intestinal contents, and, at the same time, permits the introduction of saline and glucose. When the necessity for drainage is over the tube can be removed, and as the opening into the intestine is valvular and the "sealing-off" properties of the omentum have been utilised, little or no escape of intestinal contents occurs, and all excoriation of the skin is avoided.

The results I have obtained by this method are most encouraging, and I am convinced that its use in selected cases is well worth further trial, especially as it is founded on what appears to be a sound experimental basis.

A CASE OF
INSPIRATORY APNŒA IN A NEW-BORN INFANT.

BY W. DOUGLAS KIRKWOOD, M.D. EDIN.,
AND
BERNARD MYERS, C.M.G., M.D. EDIN.,
M.R.C.P. LOND.,
PHYSICIAN TO IN-PATIENTS AT ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, ETC.
(*With Pathological Report by*
THOMAS W. LUMSDEN, M.D. Aberd.)

WE desire to record the case of a new-born infant in which there were unusual respiratory symptoms, and, as the pathological appearances in this instance were apparently similar to results obtained by Lumsden in experiments on the cat in connexion with the respiratory centres, we deemed it advisable to report the clinical symptoms and the pathological findings of this case in full for the purpose of a comparison.

The Case Described.

Birth.—The mother, aged 25, was delivered of her first child (a male) on March 18th of this year. The infant was two weeks premature. There was nothing of special interest in connexion with the birth, the labour occupying about 12 hours, but with only two to three hours' real pains; the child was born without any interference of any kind and was found to be normal in every way when examined after birth. The head did not show the slightest sign of injury. Although breathing became established immediately after birth the infant looked distinctly cyanosed for a time.

First Attack of Apnœa.—The child appeared to be normal in every way on the first day; it was rather restless on the second night after birth, and on the third day did not appear to be quite well, although so far certainly not definitely ill. About 11 A.M. it was noticed to have a sudden cessation of breathing for a short period with cyanosis, followed by resumption of normal breathing. Artificial respiration was resorted to. Several such attacks occurred at intervals.

Examination: Further Attacks.—When the child was seen by one of us (B. M.) within two hours of the first attack it appeared to be in every way a very fine specimen of a baby. On examination a little rigidity of the right arm and leg was discovered. Shortly afterwards a few *twitchings* were noticed in the right hand (within half an hour the same thing was observed in the left hand). The breathing at this time was perfectly normal. The child had passed meconium several times, which macroscopically showed no abnormality, and no blood was visible. The little patient *had* been fed by breast and had also been given Glaxo. Quite suddenly, the infant took a little deeper inspiration than usual and then ceased breathing. Cyanosis soon appeared which gradually became more marked. After about 20 seconds there were two or three short irregular respirations, after which normal breathing became re-established and the cyanosis passed off. During this period there were no convulsions or twitchings. The examination of the patient was then continued. There was no sign of congenital heart disease, nor atelectasis; the air entry into the lung was free and expansion good over all parts of the chest. Nothing of clinical importance was found in the abdomen, pharynx, nose, or neck. There was a very slight yellow tint on the skin, but practically no more than ordinary icterus neonatorum. There were no petechiæ. No increased pressure was felt at the *anterior* fontanelle. Signs of injury, hæmatoma, meningocele, or any other abnormality were absent. The temperature was normal. No ear discharge was apparent. Urine was freely passed, and the child had passed two motions in the 24 hours.

Within 15 or 20 minutes another attack was witnessed, much similar to the last, with the exception that the attack lasted for about 40 seconds, when breathing was again re-established. During this *attack* the eyes seemed to slightly point to the right and upwards for a few seconds. The tongue was normal and nothing unusual was seen in the face or position of head.

As the examination of the lungs, trachea, pharynx, and circulatory system elicited nothing to explain the condition, and Buhl's disease being in no way suggested, the symptoms seemed to be due to damage to the brain, most likely of a hæmorrhagic nature in which the respiratory centre was specially affected. The symptoms also suggested that the cortical or subcortical tissues of the left side of the brain were likewise implicated to some extent.

In the event of further attacks the nurse was instructed to perform artificial respiration, give oxygen, and sprinkle cold water on the chest. Tincture of belladonna was prescribed as a stimulant to the respiratory centre. Eight drops of brandy in a teaspoonful of water were to be given between attacks if required.

The infant seemed better for two hours, but then attacks of apnœa appeared again, the respiration ceasing in the inspiratory position for varying periods, with the appearance, as before, of cyanosis, and its disappearance after respiration had become re-established. If apnœa terminated spontaneously, it was broken by two or three short inspiratory gasps; these were succeeded by a further period of apnœa or by normal breathing. There were occasions when the baby slept for as long as one and a half hours at a time, breathing normally and appearing to be quite well. It would then wake up and have twitchings or a mild convulsion which were more marked on the right side. On one occasion, when the baby was lying on its right side, a convulsion began with a movement upwards of the eyes; at the same time the head was lifted from the pillow. When the *attacks* were over the child seemed exhausted but breathed normally. No definite sequence could be made out between the apnœa and the convulsions, as sometimes the one occurred without the other, while at other times they coincided. Each seemed independent of the *other*. *Later* on in the day the convulsions became more generalised and were heralded with a small "meningeal cry."

Death.—When artificial respiration was performed for the apnœa the latter was always cut short and normal breathing quickly re-established. *Between* the attacks the baby still looked normal. About 8 o'clock on the same day (that is, the third day after birth) the child, *having* just had a good quiet sleep, became apnœic, but resumed normal breathing with the assistance of a little squeezing. It was apparently lying quietly, its appearance for the moment giving no immediate cause for alarm, when it gave one deep inspiratory gasp and died.

It may be stated that no drugs had been given to the mother either immediately before or during labour, but *a* few whiffs of chloroform (insufficient to remove consciousness) were administered just before the birth.

An Experimental Parallel.

There have recently appeared some most interesting and cogent observations by Lumsden, who has investigated the respiratory centres in the cat, and his results seem to help materially in the elucidation of this case. In order to make the matter clear we are inserting, by kind permission of the editor of the *Journal of Physiology*,[1] two of his diagrams.* He states:—

"The theory generally held is that the automatic respiratory centre is in the lower part of the bulb, and that the regulation of impulses sent *out by it* is determined by impulses passing to it."

The following are his conclusions:—

1. "In the cat the central respiratory mechanism consists of: (*a*) A part below the striæ acusticæ which when working alone causes gasping respirations. The nerve cells producing this effect may be spoken of as the gasping centre. (*b*) A part at the level of the *striæ acusticæ* which sends out impulses causing a series of prolonged inspirations. The prolonged inspirations may be called *apneuses* and the *nerve* cells producing them the apneustic centre. (Apneusis indicating a holding of the breath in the inspiratory position.) (*c*) A part in the upper pons region which periodically inhibits the activity of the apneustic centre and so produces normal respiration. The nerve cells having this effect *may* be called the pneumotaxic centre.

2. The posterior corpora quadrigemina have in the cat no appreciable influence on respiration.

[1] Observations on the Respiratory Centres in the Cat, by Thomas W. Lumsden, M.D. (from the Department of Pathology, Lister Institute), Journal of Physiology, vol. lvii., Nos. 3 and 4.

large quantities of saline, but, taking all the available facts into consideration, I believe this beneficial result can be better explained by considering that the saline acts, chiefly at least, by diluting the toxin in the circulating blood. It has been shown[17] experimentally that injection of pilocarpine for four days, fasting for seven days, or duodenal obstruction for three days, each produces a relatively equal reduction of the quantity of water in the tissues, and yet no serious toxæmic symptoms follow either the pilocarpine injection or the fasting, whereas duodenal obstruction causes death as described above in three days. The only experimental work done on this subject in the British Isles of which I can find a record is that of Wilkie, of Edinburgh.[2] He concludes that the chief factor in producing death is dehydration of the tissues, and he bases this conclusion on the fact that, working chiefly on cats, he was unable to produce death by injecting the contents of obstructed loops into other cats. Another observer[20] has, however, found that although cats develop in obstructed loops toxic bodies similar or identical with those already described, yet they seem to be immune to injection of these bodies, though injection of the same toxic bodies obtained from cats is rapidly fatal to dogs with characteristic symptoms.

Conclusions.

I think we are justified in drawing the following conclusions from all this experimental work:—

(1) The principal factor in causing death in intestinal obstruction is a toxin which is developed chiefly in duodenum, and, although not absorbed from normal intestine, is absorbed under the conditions which prevail in obstruction.

(2) The exact chemical composition of the toxin is still under dispute, but it is almost certainly of the nature of one or other of the toxic bodies derived from protein disintegration.

(3) The exact mode of production of the toxin is also undecided, but probably the presence of pancreatic secretion, and, in a lesser degree, the activities of bacteria are necessary for its production.

(4) While the duodenum is the site of maximum toxicity in obstruction, yet the poisonous substances are developed lower down in the intestine, and it is probable that in the production of these toxins bacterial action plays an important rôle—a rôle which increases in importance the lower down the obstruction occurs.

The value of all this work and the conclusions drawn from it must finally be decided by clinical results. Do the above conclusions hold true if examined in the light of clinical experience? I believe that, for the most part, they do. In the first place, the great majority of surgeons, as the result of clinical experience and quite apart from any experimental work, are agreed that toxæmia is the chief cause of death in intestinal obstruction. Again, all are agreed as to the great benefit of large saline infusions in obstruction cases—a benefit which can be better explained by the toxæmic than by the systemic dehydration theory. Still more strongly in favour of the toxæmia theory is the fact that stomach lavage, useful as it is in all obstruction cases, is most useful in acute dilatation of the stomach. Post mortem, in most fatal cases of this condition, the duodenum is also distended, so that the functional obstruction, whatever its cause, almost exactly reproduces the conditions of many of the experiments on which the toxæmic theory is based, and the benefit of lavage may therefore be explained by the removal of the toxins generated. The same remarks apply to the well-known good results following lavage in those cases, sometimes following gastro-enterostomy, where there appears to be a temporary obstruction (probably functional and due to trauma at the operation) to the on-flow of the gastric and duodenal contents.

However, although I believe that *toxæmia* is generally the chief factor in causing death, yet I think it is rarely—if ever—the only factor. Nor does this theory explain the phenomena of many obstruction cases, for instance, in the cases of rapid death, which sometimes follow acute strangulation, the toxæmia can only be of minor importance. In strangulation we have two distinct conditions: a closed loop from which the circulation is cut off, and, above that, a part of the intestine in a condition of simple obstruction. Toxins, if formed in the closed strangulated loop, cannot be freely absorbed, while death occurs in some of these cases long before there is time for any great amount of toxin to be developed in the simply obstructed intestine above the strangulated portion. Such deaths must be due to shock. Again, it has been a common experience of mine to find on closely questioning the patients in ordinary cases of strangulated hernia that he or she vomited coincidently with the onset of pain, and then perhaps six or eight hours elapsed before any more vomiting occurred. I believe the early vomiting to be due to the temporary shock, and the later to toxæmia. For these clinical reasons, therefore, I think that shock is a more important factor in causing death than the experimental work leads one to believe, and that in some cases of strangulation it is the chief factor, producing, among other conditions, an engorgement of the portal system.

Finally, I would like to suggest that intestinal toxæmia has a large share in causing death in acute septic peritonitis. I have long believed that the fatal result is not due in most of these cases to the absorption of the products of the suppurative inflammation of the peritoneum—the symptoms preceding death are generally those of intestinal obstruction, not sepsis. To my mind, there are three factors at work in acute peritonitis: (1) shock, (2) septic absorption from the peritoneum, and (3) toxæmia from the intestine, the involved part of which is generally in a condition of paresis, producing obstruction. These three factors must be constantly increasing as the inflammation spreads. I would argue that, if the shock and toxæmia be combated, there is a possibility of prolonging the patient's life sufficiently to give the wonderful fighting powers of the peritoneum a chance of dealing with the infection. I believe that I have saved what appeared to be quite hopeless cases by not only using morphia and saline-glucose infusions to combat the shock and toxæmia, but also by directly attacking the source of the toxin by means of an enterostomy high up in the small intestine. A CASE OF INSPIRATORY APNŒA IN A NEW-BORN INFANT.

BY W. DOUGLAS KIRKWOOD, M.D. EDIN.,
AND
BERNARD MYERS, C.M.G., M.D. EDIN.,
M.R.C.P. LOND.,
PHYSICIAN TO IN-PATIENTS AT ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, ETC.
(*With Pathological Report by*
THOMAS W. LUMSDEN, M.D. Aberd.)

WE desire to record the case of a new-born infant in which there were unusual respiratory symptoms, and, as the pathological appearances in this instance were apparently similar to results obtained by Lumsden in experiments on the cat in connexion with the respiratory centres, we deemed it advisable to report the clinical symptoms and the pathological findings of this case in full for the purpose of a comparison.

The Case Described.

Birth.—The mother, aged 25, was delivered of her first child (a male) on March 18th of this year. The infant was two weeks premature. There was nothing of special interest in connexion with the birth, the labour occupying about 12 hours, but with only two to three hours' real pains; the child was born without any interference of any kind and was found to be normal in every way when examined after birth. The head did not show the slightest sign of injury. Although breathing became established immediately after birth the infant looked distinctly cyanosed for a time.

First Attack of Apnœa.—The child appeared to be normal in every way on the first day; it was rather restless on the second night after birth, and on the third day did not appear to be quite well, although so far certainly not definitely ill. About 11 A.M. it was noticed to have a sudden cessation of breathing for a short period with cyanosis, followed by resumption of normal breathing. Artificial respiration was resorted to. Several such attacks occurred at intervals.

Examination: Further Attacks.—When the child was seen by one of us (B. M.) within two hours of the first attack it appeared to be in every way a very fine specimen of a baby. On examination a little rigidity of the right arm and leg was discovered. Shortly afterwards a few twitchings were noticed in the right hand (within half an hour the same thing was observed in the left hand). The breathing at this time was perfectly normal. The child had passed meconium several times, which macroscopically showed no abnormality, and no blood was visible. The little patient had been fed by breast and had also been given Glaxo. Quite suddenly, the infant took a little deeper inspiration than usual and then ceased breathing. Cyanosis soon appeared which gradually became more marked. After about 20 seconds there were two or three short irregular respirations, after which normal breathing became re-established and the cyanosis passed off. During this period there were no convulsions or twitchings. The examination of the patient was then continued. There was no sign of congenital heart disease, nor atelectasis; the air entry into the lung was free and expansion good over all parts of the chest. Nothing of clinical importance was found in the abdomen, pharynx, nose, or neck. There was a very slight yellow tint on the skin, but practically no more than ordinary icterus neonatorum. There were no petechiæ. No increased pressure was felt at the anterior fontanelle. Signs of injury, hæmatoma, meningocele, or any other abnormality were absent. The temperature was normal. No ear discharge was apparent. Urine was freely passed, and the child had passed two motions in the 24 hours.

Within 15 or 20 minutes another attack was witnessed, much similar to the last, with the exception that the attack lasted for about 40 seconds, when breathing was again re-established. During this attack the eyes seemed to slightly point to the right and upwards for a few seconds. The tongue was normal and nothing unusual was seen in the face or position of head.

As the examination of the lungs, trachea, pharynx, and circulatory system elicited nothing to explain the condition, and Buhl's disease being in no way suggested, the symptoms seemed to be due to damage to the brain, most likely of a hæmorrhagic nature in which the respiratory centre was specially affected. The symptoms also suggested that the cortical or subcortical tissues of the left side of the brain were likewise implicated to some extent.

In the event of further attacks the nurse was instructed to perform artificial respiration, give oxygen, and sprinkle cold water on the chest. Tincture of belladonna was prescribed as a stimulant to the respiratory centre. Eight drops of brandy in a teaspoonful of water were to be given between attacks if required.

The infant seemed better for two hours, but then attacks of apnœa appeared again, the respiration ceasing in the inspiratory position for varying periods, with the appearance, as before, of cyanosis, and its disappearance after respiration had become re-established. If apnœa terminated spontaneously, it was broken by two or three short inspiratory gasps; these were succeeded by a further period of apnœa or by normal breathing. There were occasions when the baby slept for as long as one and a half hours at a time, breathing normally and appearing to be quite well. It would then wake up and have twitchings or a mild convulsion which were more marked on the right side. On one occasion, when the baby was lying on its right side, a convulsion began with a movement upwards of the eyes; at the same time the head was lifted from the pillow. When the attacks were over the child seemed exhausted but breathed normally. No definite sequence could be made out between the apnœa and the convulsions, as sometimes the one occurred without the other, while at other times they coincided. Each seemed independent of the other. Later on in the day the convulsions became more generalised and were heralded with a small "meningeal cry."

Death.—When artificial respiration was performed for the apnœa the latter was always cut short and normal breathing quickly re-established. Between the attacks the baby still looked normal. About 8 o'clock on the same day (that is, the third day after birth) the child, having just had a good quiet sleep, became apnœic, but resumed normal breathing with the assistance of a little squeezing. It was apparently lying quietly, its appearance for the moment giving no immediate cause for alarm, when it gave one deep inspiratory gasp and died.

It may be stated that no drugs had been given to the mother either immediately before or during labour, but a few whiffs of chloroform (insufficient to remove consciousness) were administered just before the birth.

An Experimental Parallel.

There have recently appeared some most interesting and cogent observations by Lumsden, who has investigated the respiratory centres in the cat, and his results seem to help materially in the elucidation of this case. In order to make the matter clear we are inserting, by kind permission of the editor of the *Journal of Physiology*,[1] two of his diagrams. He states:—

> "The theory generally held is that the automatic respiratory centre is in the lower part of the bulb, and that the regulation of impulses sent out by it is determined by impulses passing to it."

The following are his conclusions:—

1. "In the cat the central respiratory mechanism consists of: (*a*) A part below the striæ acousticæ which when working alone causes gasping respirations. The nerve cells producing this effect may be spoken of as the gasping centre. (*b*) A part at the level of the striæ acousticæ which sends out impulses causing a series of prolonged inspirations. The prolonged inspirations may be called apneuses and the nerve cells producing them the apneustic centre. (Apneusis indicating a holding of the breath in the inspiratory position.) (*c*) A part in the upper pons region which periodically inhibits the activity of the apneustic centre and so produces normal respiration. The nerve cells having this effect may be called the pneumotaxic centre.

2. The posterior corpora quadrigemina have in the cat no appreciable influence on respiration.

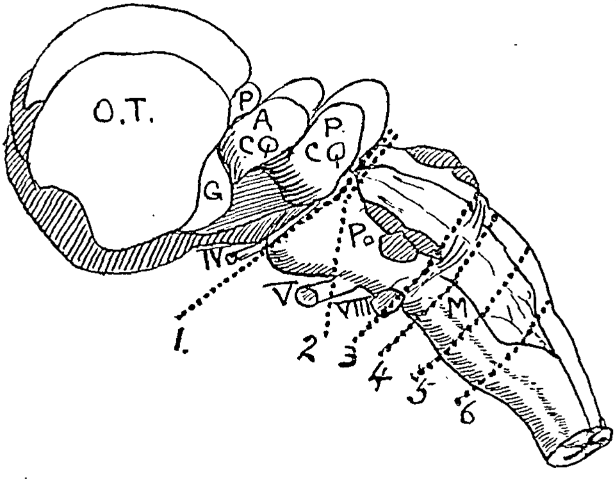
He states further:—

“*Section in the Upper Part of the Pons.*—A section along line 2, Fig. 1, or at any point between lines 2 and 3, causes instantaneously a full development of the inspiratory type of breathing, and this happens whether the fifth and tenth nerves have been cut or not; a slow deep inspiration is taken, and the inspiratory position is held for two or even three minutes. During the last part of the time the muscles relax slowly, and finally give way suddenly. Two or three relatively quick respirations of abnormal type are then taken. Following these there is again a prolonged inspiration and so on. The cycle repeats itself with great regularity for, it may be, two or three hours, but the duration of the inspirations gradually lessens. The blood-pressure tracing taken simultaneously (Fig. 3 in *Journal* but Fig. 2 here) shows that during prolonged inspiration the arterial pressure first rises and later sinks to a low level. It rises again rapidly during the short period of relatively quick respirations.” “Section between lines 5 and 6 causes the cessation of all respiratory movement and death.”

FIG. 1.—*Diagram of Brain-Stem showing Level of Crucial Sections (Cat).*



Level 1, just behind posterior corpora quadrigemina dorsally and above pons ventrally; 2, dorsally same at Level 1, ventrally at mid-pons; 3, just above striæ acousticæ; 4, just below striæ acousticæ; 5, half way between 4 and 6; 6, just above angle of calamus scriptorius. The pneumotoxic centre is placed between 1 and 2. Apneustic centre between 3 and 4. Gasping centre between 5 and 6.

Lumsden adds:—

“ . . . When an animal which has been so nearly dead as to cease breathing is revived by means of artificial respirations, the respiration returns in the reverse order (to the effect of asphyxia or anæsthetics on animal dying from same) a preliminary period of gasping is followed by a series of prolonged inspirations which gradually shorten until they become indistinguishable from slow natural breathing, and soon the normal respiratory rhythm is resumed.”

Morbid Anatomy in the Authors' Case.

It appeared to us that Lumsden's experiments on the brain-stem of the cat were likely to shed light as to the cause of death of this infant. It was most fortunate, therefore, that he was able personally to investigate the brain-stem of this case.

Report by Dr. T. W. LUMSDEN.—“No signs of purpura were visible. On opening the cranium, the vessels on the pia were found to be much dilated and there were a number of subpial punctiform hæmorrhages both on the convexity of the brain and on the walls of the lateral ventricles. The choroid plexuses were intensely injected. The minute hæmorrhages above-mentioned were entirely superficial and there was no escape of blood into the ventricles. There was nothing abnormal to the naked eye in the regions of the pons or medulla. On section of the brain the grey matter was pinker than usual, even in a new-born baby. The brain was carefully opened and placed in formalin for 48 hours, after which it was examined by slicing it and the brain-stem at intervals of about 1 cm., but nothing further abnormal was found.

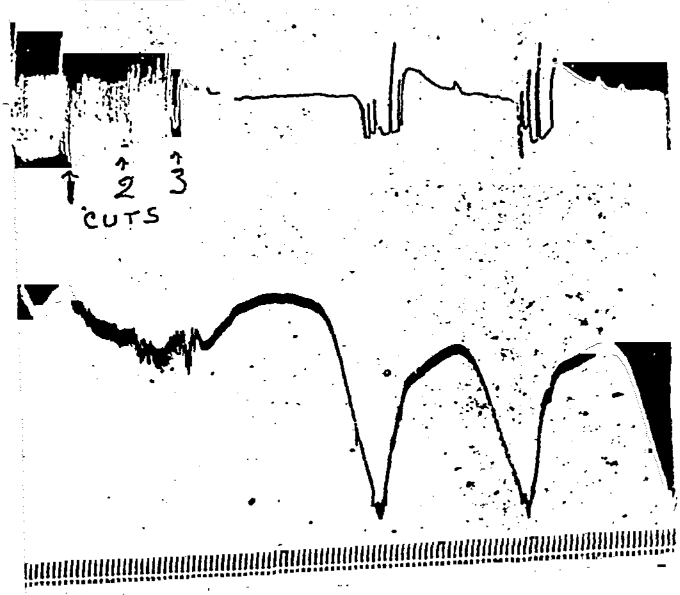
It may be well to state categorically that there was no evidence of meningitis or of gross hæmorrhages into the meninges, the ventricles, or the brain substance. The whole brain-stem and mid-brain, with small portions of the cortex and cerebellum, were preserved for minute examination.

The abdominal and thoracic organs appeared healthy.”

Microscopic Observations.—“But for the universal congestion of all blood-vessels, the portions of the cortex and cerebellum examined and the mid-brain appeared healthy. The brain-stem, stained by Bielschowsky's method and counter-stained with acid fuchsin and methylene-blue, was examined exhaustively in serial section. A few very minute capillary ecchymoses were seen in the upper part of the pons and all the capillaries were much dilated, but except in the area just above the striæ acousticæ serious extravasation had not taken place. Into this region—just above the level of the olivary bodies and constituting the lower 2 mm. of the pons—five or six small hæmorrhages had occurred. The largest of these measured 2 × 1·5 × 1·25 mm. At its lower extremity it surrounded the apex of the right olive, and thence extended for 2 mm. upwards, outwards, and backwards towards the restiform body. This hæmorrhage caused damage to the formatio-reticularis, fillet, a small portion of the seventh nerve nucleus, and some fibres of the trapezium. A second extravasation of almost equal size was found in a nearly symmetrical situation on the left side.

Several other minute hæmorrhages were seen at this level in the formatio reticularis and in the restiform body. If one may apply to man the results obtained in cats[2] the hæmorrhages described above would temporarily, at any rate, have the same effect as section of the brain-stem just above the striæ at level 3, Fig. 1, and would determine the onset of the apneustic type of respiration, which is characterised by alternating periods of inspiratory tonus and gasping (Fig. 2).

FIG. 2.—*Respiration and Blood-Pressure Tracings in a Cat.*



Cut 1 was through the mid-brain; cut 2 at section 1, Fig. 1; cut 3 at section 2, Fig. 1. Inspiration upwards abscissa 12 mm. below time tracing (5 seconds).

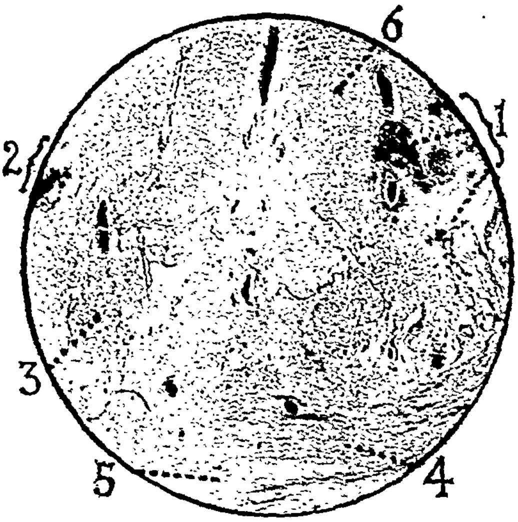
In a series of ten cats in which the seventh and eighth nerves were severed intracranially, death, preceded by apneustic respiration and convulsions, resulted. That these results were not directly due to severance of the seventh and eighth nerves but to accidental hæmorrhages into the striæ region from dragging on the nerves, was conclusively proved. It was found that these nerves could be destroyed from the external auditory meatus without affecting the breathing, and if great care is taken not to drag on them the seventh and eighth nerves can, after removal of the cerebellum, be divided intracranially without causing pontine hæmorrhages or respiratory symptoms.

---

[2] Journal of Physiology, March, 1923.

It is not clear why hæmorrhages occurred in this case, but the feline experiments referred to above indicate that the pontine damage was sufficient to cause death by interference with the respiratory centres situated in the brain-stem above and at this level."

FIG. 3.—*Transverse Section of Brain-Stem just above Striæ Acousticæ.*



1. Largest hæmorrhage. 2. Smaller extravasation on left side. 3. Left pyramid. 4. Transverse fibres of lowest part of pons. 5. Median raphé with many dilated blood-vessels. 6. Right fillet. The unnumbered black spots are distended blood-vessels. Where a white space is seen, blood-clot has fallen out of a vessel or extravasation during section. (Microphotograph × about 10.)

Reference to Other Cases.

It is interesting to note that Still[3] records five cases of a somewhat similar nature. Four were boys; three were in the fourth to the eighth pregnancy. The attack came on without any reason while the infant was lying quietly in its cot. The onset was silent, without distress, and the infant simply ceased to breathe during the apnœic period. The infant had a healthy colour between the attacks, but there was some cyanosis during the attacks. In one of his cases there were four attacks in one day and two the next, and then the attacks ceased and the child recovered. In another there were six or seven attacks in the 24 hours and these continued to recur for seven days before death took place. In Still's cases one out of five recovered. On two of his cases there were necropsies; one showed some collapse of the bases and commencing broncho-pneumonic process, another case showed extensive atelectasis. He was of opinion that these might just as well have resulted from the condition as have caused the attacks. It seemed to him that the condition was more suggestive of some affection of the respiratory centre than of any secondary asphyxia from any insufficient expansion of the lung.

It is not difficult to imagine how over-lying or even foul play might be suspected in a case of this nature under certain circumstances. Looking back on several cases which have occurred in our experience during the last 25 years, we can recollect a few which had symptoms very similar to those described in the case under consideration. It is not unlikely that such cases are a little more frequent than might be supposed.

Cruickshank[4] draws attention to the pressure of the contracting uterine walls on the infant, also to the effects of accidental hæmorrhage, occlusion of umbilical vessels from twisting or prolapse. He states that the heart, continuing to beat, congestion becomes more marked, and that if no relief be obtained the congestion becomes so great that certain of the smaller vessels give way and petechiæ and capillary oozings appear in various situations. All these effects, he states, may be produced by asphyxial congestion alone, quite apart from the additional trauma of labour. He adds: "It is not surprising to find, then, that in a very large number of cases such hæmorrhages do exist." He is of the opinion that asphyxial congestion is the most usual factor in producing hæmorrhage, the pressure of the maternal passages being also very important, while "injuries due to abnormalities of presentation or to operative interference occupy the third, though still one of the important places in the ætiology of these lesions." We quite agree with Cruickshank that probably many infants with quite extensive birth hæmorrhages are born alive and survive, some perhaps to die from broncho-pneumonia and other common childish disorders later on.

Summary.

The important points are: The mother is a healthy primipara, aged 25, who enjoyed excellent health during pregnancy and labour. The labour was comparatively easy and natural. No drugs were given her; a few whiffs of chloroform just before the birth of the child only. There is no similar case in family. Cyanosis was present at birth, but passed off.

There was no asphyxia neonatorum. The infant was well formed, showed no abnormalities, and looked healthy. It took its food well and passed meconium and urine without trouble. There were slight although definite changes noted in the infant within the first 24 hours. These gradually increased in intensity.

Definite attacks of apnœa before the infant was two days old. Heart, lungs, air-passages normal. Twitchings and then convulsions. The infant looked well, and was of good colour, between attacks of apnœa; the cyanosis was only present during attacks. The effect of artificial respiration in cutting short the attacks.

Death within 12 hours of the first appearance of apnœa. The total number of attacks must have been more than a dozen.

Were the convulsions due to the slight changes found on the cortex cerebri or to respiratory failure? The clinical symptoms suggested an affection of the respiratory centre, yet at the necropsy there was comparatively little evidence macroscopically. Indeed, if it had not been for Thomas Lumsden's recent observations in the cat no further investigations would have been proceeded with.

The demonstration by Lumsden of hæmorrhages in the pons which first affected the pneumo-taxic and later the apneustic centres, causing death from respiratory failure. No changes were found in the heart or lungs post mortem. There were no signs of purpura.

The existence of greater frequency of hæmorrhages in the new-born, which was shown by Cruickshank, than has probably generally been entertained and therefore the likelihood that tiny hæmorrhages into the pons are perhaps not so infrequent in new-born infants as most observers believe.

That hæmorrhage into the pons is doubtless an unrecognised cause of death in certain infants.

Taking Still's reported five cases this one makes a fatality of five out of six.

It will be interesting to note if the after-history of cases which recover from this condition show demonstrable changes in the central nervous system.

The necessity of keeping the apnœic attacks in mind in deaths in newly-born infants thought to be due to over-lying or foul play.

The treatment in a definite case would appear to consist of artificial respiration and the use of oxygen during the attacks; keeping the child quiet and seeing that the bowels are kept properly open.

The prophylactic treatment obviously commends itself in the prevention of undue cerebral congestion

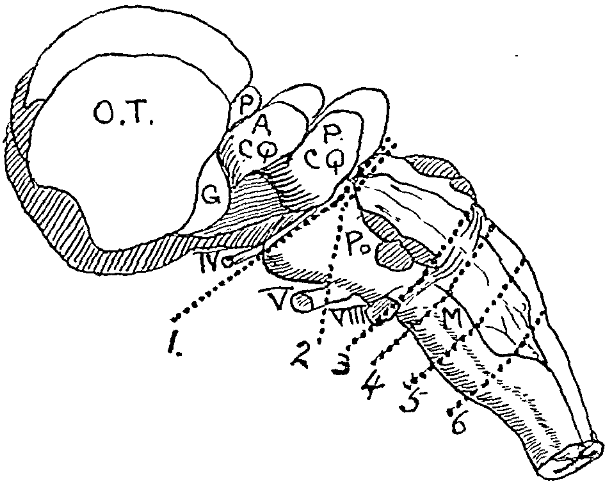
He states further:—

"*Section in the Upper Part of the Pons.*—A section along line 2, Fig. 1, or at any point between lines 2 and 3, causes instantaneously a full development of the inspiratory type of breathing, and this happens whether the fifth and tenth nerves have been cut or not; a slow deep inspiration is taken, and the inspiratory position is held for two or even three minutes. During the last part of the time the muscles relax slowly, and finally give way suddenly. Two or three relatively quick respirations of abnormal type are then taken. Following these there is again a prolonged inspiration and so on. The cycle repeats itself with great regularity for, it may be, two or three hours, but the duration of the inspirations gradually lessens. The blood-pressure tracing taken simultaneously (Fig. 3 in *Journal* but Fig. 2 here) shows that during prolonged inspiration the arterial pressure first rises and later sinks to a low level. It rises again rapidly during the short period of relatively quick respirations."
"Section between lines 5 and 6 causes the cessation of all respiratory movement and death."

FIG. 1.—*Diagram of Brain-Stem showing Level of Crucial Sections (Cat).*



Level 1, just behind posterior corpora quadrigemina dorsally and above pons ventrally; 2, dorsally same at Level 1, ventrally at mid-pons; 3, just above striæ acousticæ; 4, just below striæ acousticæ; 5, half way between 4 and 6; 6, just above angle of calamus scriptorius. The pneumotoxic centre is placed between 1 and 2. Apneustic centre between 3 and 4. Gasping centre between 5 and 6.

Lumsden adds:—

". . . When an animal which has been so nearly dead as to cease breathing is revived by means of artificial respirations, the respiration returns in the reverse order (to the effect of asphyxia or anæsthetics on animal dying from same) a preliminary period of gasping is followed by a series of prolonged inspirations which gradually shorten until they become indistinguishable from slow natural breathing, and soon the normal respiratory rhythm is resumed."

Morbid Anatomy in the Authors' Case.

It appeared to us that Lumsden's experiments on the brain-stem of the cat were likely to shed light as to the cause of death of this infant. It was most fortunate, therefore, that he was able personally to investigate the brain-stem of this case.

Report by Dr. T. W. LUMSDEN.—"No signs of purpura were visible. On opening the cranium, the vessels on the pia were found to be much dilated and there were a number of subpial punctiform hæmorrhages both on the convexity of the brain and on the walls of the lateral ventricles. The choroid plexuses were intensely injected. The minute hæmorrhages above-mentioned were entirely superficial and there was no escape of blood into the ventricles. There was nothing abnormal to the naked eye in the regions of the pons or medulla. On section of the brain the grey matter was pinker than usual, even in a new-born baby. The brain was carefully opened and placed in formalin for 48 hours, after which it was examined by slicing it and the brain-stem at intervals of about 1 cm., but nothing further abnormal was found.

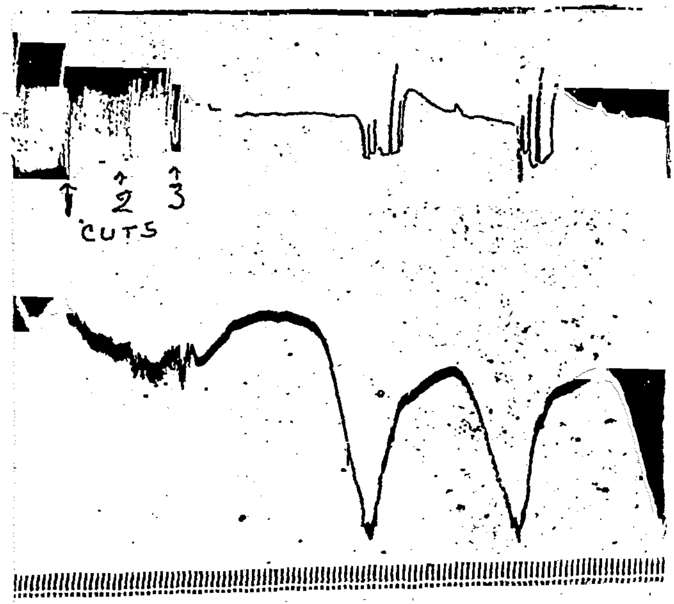
It may be well to state categorically that there was no evidence of meningitis or of gross hæmorrhages into the meninges, the ventricles, or the brain substance. The whole brain-stem and mid-brain, with small portions of the cortex and cerebellum, were preserved for minute examination.

The abdominal and thoracic organs appeared healthy."

Microscopic Observations.—"But for the universal congestion of all blood-vessels, the portions of the cortex and cerebellum examined and the mid-brain appeared healthy. The brain-stem, stained by Bielschowsky's method and counter-stained with acid fuchsin and methylene-blue, was examined exhaustively in serial section. A few very minute capillary ecchymoses were seen in the upper part of the pons and all the capillaries were much dilated, but except in the area just above the striæ acousticæ serious extravasation had not taken place. Into this region—just above the level of the olivary bodies and constituting the lower 2 mm. of the pons—five or six small hæmorrhages had occurred. The largest of these measured 2 × 1·5 × 1·25 mm. At its lower extremity it surrounded the apex of the right olive, and thence extended for 2 mm. upwards, outwards, and backwards towards the restiform body. This hæmorrhage caused damage to the formatio-reticularis, fillet, a small portion of the seventh nerve nucleus, and some fibres of the trapezium. A second extravasation of almost equal size was found in a nearly symmetrical situation on the left side.

Several other minute hæmorrhages were seen at this level in the formatio reticularis and in the restiform body. If one may apply to man the results obtained in cats[2] the hæmorrhages described above would temporarily, at any rate, have the same effect as section of the brain-stem just above the striæ at level 3, Fig. 1, and would determine the onset of the apneustic type of respiration, which is characterised by alternating periods of inspiratory tonus and gasping (Fig. 2).

FIG. 2.—*Respiration and Blood-Pressure Tracings in a Cat.*



Cut 1 was through the mid-brain; cut 2 at section 1, Fig. 1; cut 3 at section 2, Fig. 1. Inspiration upwards abscissa 12 mm. below time tracing (5 seconds).

In a series of ten cats in which the seventh and eighth nerves were severed intracranially, death, preceded by apneustic respiration and convulsions, resulted. That these results were not directly due to severance of the seventh and eighth nerves but to accidental hæmorrhages into the striæ region from dragging on the nerves, was conclusively proved. It was found that these nerves could be destroyed from the external auditory meatus without affecting the breathing, and if great care is taken not to drag on them the nected to a further short piece of tubing by a metal elbow. Movement of the patient's head by the surgeon, however, or pressure on the lower jaw, may cause obstruction of the pharyngeal end of this tube at any time with some of the undesired effects described above. The satisfactory results obtained by passing an expiratory tube into the trachea alongside the catheter have led me to adopt this procedure where possible in every case in which endotracheal insufflation is the method of choice. Expiration as well as inspiration is brought directly under the control of the anæsthetist, and the pharynx can be as effectively plugged as desired.

---

[2] *Journal of Physiology*, March, 1923.

When the mouth is available for the administration, catheter and expiratory tube can be fastened together and passed in one manœuvre. When the nose is the available channel, the catheter is passed through one nostril and the expiratory tube through the other, each being picked up in the oral pharynx with a forceps for the purpose[1] and passed into the trachea by direct vision. A suction pump is used in conjunction with this method to maintain a clear field when there is bleeding into the mouth or nose.

The course of the anæsthesia when conducted in this way is, in my experience, smoother than when a catheter alone is used, and its advantage to the surgeon is obvious. I understand that double channel catheters are used in some continental clinics, but in this country I have been unable to obtain any of sufficient (double) calibre for the purpose.

Sidcup.

ACUTE KETOSIS DURING PREGNANCY.

BY J. HARGREAVES ROBINSON, L.A.H. DUB., L.M.R.C.P. IREL.

THE following case of acute ketosis of pregnancy is of interest by reason of its sudden and acute onset, and the happy issue under appropriate treatment.

A primipara, aged 32, during the seventh month of pregnancy developed a rapidly increasing anasarca in a few hours. Previous health excellent. Urine: amber colour, reaction acid, sp. gr. 1010. Albumin, trace; sugar, nil. Symptoms quickly increased in severity. There was cough due to œdema of the larynx, aphonia, lethargy, fibrillary tremors, pain and stiffness of the joints, irregular respiration during sleep, almost of the Cheyne-Stokes type, large circumscribed patches of transient erythema, severe stabbing pains in the hepatic region, sour taste, odour of acetone from the breath, spongy gums, sordes, ocular phenomena, which are now subjectively described as "something like the effect produced by opening the eyes under water and seeing for an instant moving shadows." Unilateral œdema of the face after sleeping on the side. Fœtal activity.

I am indebted to Dr. Cronin Lowe for the following report on the urine: Albumin present, but too small a quantity to estimate; reaction acid; acetone present; diacetic acid present; urea, 0·77 per cent.; ammonia, 0·15 per cent.; ammonia coefficient, 1 to 5·1. Centrifuged deposit: Pus cells, a few; blood cells, nil; casts, nil; epithelial cells present.

The clinical condition increased in severity, and Dr. Leith Murray passed bougies into the uterus to induce labour. On removal of the bougies the membranes were ruptured, and six hours later Dr. Philip Vickers delivered with forceps without an anæsthetic. Two sutures (20 day chromic catgut) were inserted into the perineum; they dissolved out on the fifth day, and left a peculiar depressed areola about ¼ in. in diameter at the site of insertion. Sodii bicarb. ¼ lb. was given during the three days preceding delivery. The following were also given: Calcium lactate ½ drm. daily; ol. ricini 2 oz. at the onset of the condition; 12 hours later sodii sulphas ¼ oz., and subsequently 1 drm. doses three-hourly; rectal salines. The urine became alkaline four days after delivery. The infant (weight 5 lb. 6 oz.) showed transient patches of erythema during the first week after birth. In consequence of the small capacity of the stomach at birth the infant was fed two-hourly on undiluted cow's milk, with sodii citras 3½ gr., gradually increased to 6 gr. in each feed. Eleven feeds in the 24 hours. Body-weight at 14 weeks, 13 lb.

The mother's recovery was uneventful.

Southport.

BRONZED DIABETES:

ITS REACTION TO DIETETIC AND INSULIN TREATMENT.

BY E. BOSDIN LEECH, M.D. CAMB., F.R.C.P. LOND.,
HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

THE origin of bronzed diabetes is still unknown. The case here recorded was not diagnosed till after death, and during life the patient received the modern diabetic treatment as carried on at the Manchester Royal Infirmary. It is of interest to see how he responded to that treatment.

A male, aged 47, was admitted to hospital on May 5th, 1923, with acute diabetes of three months' standing. During life there was no definite skin pigmentation and the skin was sallow or possibly slightly icteric. From May 9th to June 12th he was treated dietetically on the lines of the Allen treatment. May 9th to 11th, preliminary diet; 12th to 15th, fluid (starvation) diet. On this the sugar disappeared. The caloric value of the food was then gradually raised, but sugar appeared on the 18th (with 327 cal.), 22nd (360 cal.) lasting four days; June 4th (952 cal.) and 8th (952 cal.). The blood-sugar results during this time were: May 9th 0·2816 per cent., 29th 0·1968 per cent.; June 10th 0·2816 per cent. About the last-named date the patient developed œdema and ascites, and it was evident that he was not going to improve with simple dietetic treatment. It had not been possible to train him up to take even 952 calories daily. Insulin was therefore given, 15 units daily, 10 at 8.30 A.M. and 5 at 6.30 P.M. A diet was given with caloric value 2183, later reduced to 1683. With this a trace of sugar persisted. Numerous blood-sugar estimations varied from 0·0625 on the first day of insulin treatment to 0·2062 on June 19th.

The patient never showed any improvement with the insulin, but became weaker, more emaciated, and more water-logged. On June 25th he refused food and the insulin was of necessity discontinued. He died on the 27th.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

MATERNITY AND CHILD WELFARE GROUP.

A MEETING of this group was held on July 3rd at 117, Piccadilly, W., Dr. H. K. WALLER, the retiring President, being in the chair.

In the absence of Prof. E. MELLANBY, Dr. ERIC PRITCHARD opened a discussion on the

Feeding of Infants between the Ages of 1 and 5 Years.

He said that during the last ten years more important discoveries had been made as regards diet than in the previous 10,000 years. The present knowledge was derived chiefly from animal experimentation, since many generations of animals could come under observation, whereas the difficulty of working with humans was that the results of indiscretions were not shown in one generation; in vitamin deficiency, for example, it might take long before any change was noticeable. At the beginning of the study of scientific dietetics energy value of food was alone regarded as important, on the analogy of the needs of a machine. This analogy was true in many respects, but no machine was able to repair, enlarge, modify, or reproduce itself, and if some were made to lubricate themselves they could not, at any rate, clean, stimulate, and protect themselves against external injuries. The human body was required to do all these things and diet had to provide much besides energy value. Milk was an adequate and sufficient food for the human body for the first 12 months of life. The biological value of proteins was now known to differ greatly, and attempts made to classify foods on this basis resulted in a table in which meat stood highest, from too prolonged a labour on the one hand and the avoidance of undue interference on the other. Even most careful steering between Scylla and Charybdis would probably not prevent some cases; possibly there is an innate peculiarity of the blood-vessels in them. Again, we know that some infants who have suffered from fairly bad asphyxia neonatorum show no abnormality later in life. It would be interesting to hear the views of others who have had *similar cases.*

Our thanks are due to Dr. Lumsden for the great help he has given, not only by his observations on cats, but by his investigations in this case.

THE MODE OF TRANSMISSION OF MALARIA:

A HYPOTHESIS ADVANCED BY RICHARD PFEIFFER IN 1892.[1]

BY C. M. WENYON, C.M.G., C.B.E., M.B., B.S., B.SC. LOND.,

DIRECTOR OF RESEARCH IN THE TROPICS TO THE WELLCOME BUREAU OF SCIENTIFIC RESEARCH.

OF the various conjectures on the mode of transmission of malaria which were made prior to the work of Manson and Ross, and the actual demonstration of the mosquito cycle of the parasite of this disease, that of Richard Pfeiffer appears to be the one most logically argued, most accurately deduced, and nearest the truth in the light of subsequent discoveries. Pfeiffer's remarks appear to have been entirely overlooked, probably because they were included in a paper dealing with another subject. The accuracy of Pfeiffer's reasoning is remarkable. It was based on the knowledge gained from a study of the common coccidium of the rabbit, and the scientific mind of Pfeiffer realised the possibility of the parasite of malaria having a similar life-cycle which completed itself, not on the ground in a protective oöcyst, but in the body of some blood-sucking invertebrate which might inoculate the germs thus produced into human beings. The similarity of the reproductive phase of the coccidia in the epithelial cells which they destroyed and that of the malarial parasite in the red blood corpuscles, together with the absence, in the case of the malaria parasites, of any resistant stage which could compare with the oöcysts of coccidia, led Pfeiffer to the view that in some blood-sucking insect lay hidden the secret of the transmission of malaria.

During the years 1889–90 this observer occupied himself with a study of the common coccidium of the rabbit. His paper, illustrated by excellent microphotographs, was published in 1892, and forms a landmark in our knowledge of these parasites. Hitherto it had been assumed that the sporulation of coccidia in the epithelium, and that in the oöcyst after it had left the body, represented two distinct parasites. To Richard Pfeiffer is due the credit of having first demonstrated that these were merely phases of one and the same organism. Sporulation in the epithelium led to multiplication within the host, while that in the oöcyst had to do with the spread of infection to another animal. The resistant oöcyst protected the parasite during its development outside the body. To Pfeiffer the endogenous sporulation of coccidia and malarial parasites were alike, while the absence of an oöcyst in the latter suggested the possibility of the exogenous cycle taking place while protected by some insect's body.

The following is a fairly literal translation of the final paragraph of Pfeiffer's most interesting and important work on the coccidia of the rabbit:—

> As a result of the discoveries of Laveran, Marchiafava, Celli, and Golgi, it is known that in malarial fever the red blood corpuscles harbour characteristic motile amœboid bodies which increase in size, bring about destruction of the occupied cell, and then, at regular intervals, as a result of segmentation associated with the formation of a residual body, produce numerous young individuals, which in their turn always give rise to a new generation of blood parasites. So far all is clear. But how does the parasite gain entrance to the human body? It is possible to produce the fever in healthy men, as was first shown by Gerhardt, by the injection of small quantities of blood from a person suffering from malaria. Without going into this matter further, it is clear that *under no condition can this be* the normal mode of infection. On the other hand, all epidemiological experience indicates a close connexion between marsh-fever and special conditions of the soil. *The first and most* evident idea was that in some way the blood parasite concerned was present in the soil or in the water of the infected locality, and that it attacked man as a result of inhalation or by way of the digestive tract. But all investigations which have been conducted *along this* line have remained without result. This is no longer surprising since we have learnt that the blood parasitising protozoa are extraordinarily delicate, and are entirely unsuited for a free life in the *outer* world. *Grassi's* hypothesis that the widely distributed amœbæ of marsh water enter the blood of man, transform themselves into malarial parasites and, as a result of adaptation to the existing conditions, lose their power of existing as free living organisms, is *based on so forced a supposition and receives* so little support from experiment, that it does not indicate a way out of the prevailing difficulty. How then is the undoubted dependence of malarial infection on environment to be explained? The following solution suggests *itself, but I bring it forward only as a* hypothesis, the justification for which rests in the fact that it indicates a line of investigation. It is possible that in the case of the malarial parasite also there exists an exogenous phase, *a* developmental cycle which completes itself outside the human host, possibly in the body of a lower animal (as, for instance, certain insects) and possibly also, in part at least, in the soil. This exogenous malarial germ could then be conveyed to man through *the air or water, or as* Robert Koch has *remarked* to me, through the sting of blood-sucking insects.

The reasoning is so sound, and has been so completely justified by subsequent investigations, not only on the life-history of the malarial parasite itself, but also by the discovery of the close relationship which exists between malarial parasites and coccidia, that it seems *worth while to call* attention to Pfeiffer's remarks.

Clinical and Laboratory Notes.

THE PROVISION FOR EXPIRATION IN ENDOTRACHEAL INSUFFLATION ANÆSTHESIA.

BY I. W. MAGILL, M.B., B.CH., B.A.O. BELF.,

SENIOR ANÆSTHETIST, QUEEN'S HOSPITAL, SIDCUP; HONORARY ANÆSTHETIST, BROMPTON HOSPITAL FOR CONSUMPTION.

THE value of endotracheal insufflation anæsthesia for operations in the region *of the* head and neck is *too* well known to require any comment. In certain cases, however, particularly those in which the method is specially indicated—namely, *operations* involving the *lower* jaw and mouth—lack of adequate provision for expiration may, by its effect on the patient, interrupt the course of a smooth *anæsthesia* or embarrass the work of the surgeon.

(1) With regard to the patient, partial respiratory obstruction due to *the falling back of the tongue*, pressure *on* the lower jaw, or other cause, may produce a form of hyperpnœa with laboured expiration, consequent congestion, and increased *hæmorrhage* at the site of the operation.

(2) With regard to the surgeon, to operate under the full force of the patient's anæsthetic-*laden* expirations is *at least* unpleasant. When there is bleeding into the mouth or upper air-passages the additional accompaniment of a spray of blood is unlikely *to* assist either his *temper* or his technique.

These effects may be counteracted in many instances by means of a firm-walled rubber tube of *sufficient* calibre passed into the pharynx through the mouth or nose, according to the site of the operation, and con-

Reviews and Notices of Books.

ENCYCLOPÆDIA MEDICA.

Second edition. Vol. IX., Mammillaplasty to Obesity. General Editors, Vols. I.–VIII., the late J. W. BALLANTYNE, M.D., C.M., F.R.C.P.E.; Vol. IX., ALEXANDER GOODALL, M.D., F.R.C.P.E. London and Edinburgh: W. Green and Son, Ltd. 1923. Pp. 672. 30*s*.

Dr. J. W. Ballantyne, who edited the first eight volumes of the second edition of the Encyclopædia Medica, died in January last, and this regrettable event has, we are informed, delayed the appearance of this volume. The references in many of the articles are, indeed, not to very recent work, though the spirit of most of them is modern. The publishers announce that they were able to secure the editorial services of Dr. Alexander Goodall, for the completion of this and the remaining volumes of the series, of which the publication is expected to be completed next year. Vol. IX. maintains the standard of previous instalments. Notable among those articles revised by the original authors are those on Forensic Medicine, by Prof. Harvey Littlejohn, on Infections of the Nails, by Dr. George Pernet, on Occupation Neuroses, by Dr. Wilfred Harris, and on Acute Inflammations of the Nose, by Mr. Herbert Tilley. It is natural that auto-revision should give the best result, for the introduction of a revising hand, although essential in certain cases, can hardly fail to alter, though perhaps very slightly, the point of view of the original writer. Specially successful, however, is the revision by Dr. C. B. Ker of the section on Epidemic Cerebro-Spinal Meningitis by the late Sir William Osler, and that by Dr. W. A. Potts on Mental Deficiency, written by Dr. G. E. Shuttleworth. New articles are those on Military Surgery, by Sir D'Arcy Power, Mycetoma, by Major W. S. Patton, I.M.S. (ret.), and Neurasthenia, by Dr. Ivy M'Kenzie. We regret that the list of principal articles in the volume, with the names of authors or revisers, is not supplemented by an index of the authors of short articles on subjects of smaller range though by no means necessarily of less importance. Some of these shorter articles, notably one on Masturbation, appear to be most admirable summaries of the subject dealt with, and since the views expressed are not free from controversy, an indication of the name of the author would give confidence to those who hold the same opinions. This is almost the only omission in an admirable volume.

CLINICAL DIAGNOSIS OF INTERNAL DISEASES.

By LLEWELLYS F. BARKER, M.D., LL.D., Professor of Clinical Medicine, Johns Hopkins University. In three volumes. London and New York. D. Appleton and Co. 1923. Pp. 2908. £5.

THESE three volumes originally formed part of a series of six, entitled Monographic Medicine, published in 1916. In a foreword it is stated that they have been republished separately in response to "requests from various quarters." The first feeling produced on looking through the republished volumes is curiosity as to what could have formed the subject-matter of the remainder; for Prof. Barker takes all medical knowledge for his province, even including in his monograph conditions such as ringworm and chronic mastitis, which hardly seem to merit the designation "internal." In an introduction, written in 1916, the author points out that the present-day physician, or "internist" as he prefers to call him, is, or at any rate should be, engaged in "attempting to visualise clearly the functional pathological processes that are the essence of disease." His aim in writing has been to supply information as to methods and procedures available for following these functional pathological processes. This involves the description of the means employed in the investigation of cases in all the fields of medicine, an undertaking of such vast extent that it is amazing that one man should have been found capable of attempting it. That Prof. Barker did attempt it single-handed was due to his belief that "the problems of selection of matter for such a work as the present are such that they can best be met by one man, provided that he has had large clinical experience, some years of laboratory training, and has always been in close touch with clinical workers." Such a man—we had almost said superman—the author would certainly appear to be, and in 1916 the present work must have been nothing short of prodigious. The whole field of diagnosis was covered, so far as it had then been mapped—roentgenology, bacteriology, hæmatology, biochemistry, and biophysics; with all of them the author displayed an equal and astonishing familiarity, and laid before his readers the fruits of the latest work. But that was in 1916, and now it is 1923, and the volumes have apparently been reprinted without further comment, without withdrawal or addition, and with no reference under seven years' old.

Perusal of the work to-day is, in some respects, encouraging. It serves to convince that in spite of cavillers, medicine, so far at any rate as diagnosis is concerned, does move. Prof. Barker's work was in the very forefront of the advancing tide in 1916; in 1923 that tide has flowed far beyond. No doubt it has carried a good deal of worthless flotsam with it, but it has also borne many things of real value. Among these may be mentioned the newer knowledge of the accessory food factors and their relation to the deficiency diseases; the recognition of the curative powers of the actinic rays of sunlight in rickets; the more recent methods of estimating the sugar in the blood, which have made it possible for even the general practitioner with some biochemical training to distinguish true diabetes from the various glycosurias and to follow the condition of his diabetic patients as never before; the simplified urea tests for the gauging of renal functions; the estimation of thyroid overaction or deficiency by observations on the basal metabolism—and the list might be prolonged a good deal further.

It is justifiable to question the wisdom of Prof. Barker in allowing his book to be reprinted even in response to the urgency of its admirers until he or someone else had brought it up to date. It would be unkind further to insist upon the lapses of omission and inclusion incident upon the production in 1923 of a work completed in 1916, and apart from these nothing but matter for admiration remains in Prof. Barker's book. The descriptions of all the well-established clinical methods are excellent. In his zeal for more modern methods the author has not neglected the older modes of investigation, and his description of physical signs of all types and descriptions are masterly. On the main clinical features of every disease he may wish to investigate the practitioner or student could have no better guide than Llewellys Barker.

MEDICAL DIETETICS.

Vorlesungen über Diätbehandlung innerer Krankheiten. Fourth edition. By Prof. H. STRAUSS, Berlin Jewish Hospital. Berlin: S. Karger. 1922. Pp. 471.

Prof. H. Strauss's volume, which has reached a fourth edition, gives in the form of 17 lectures a thoughtful and thorough exposition of the principles which should guide the physician in prescribing food in the commoner diseases. The dietetic treatment of alimentary disorders naturally takes up a good part of the volume. But circulatory and kidney diseases, gout, diabetes, obesity, infectious diseases, and post-operative diets also receive full attention. The tables of analyses at the end are exhaustive and are cast into a useful form, giving the calories, protein, fat, carbohydrate, and water in 100 g. of each food, both raw and as served at the table. Special mention must be made of the valuable appendix of hints for the dietetic kitchen by Elise Hannemann. This contains nearly 100 pages of good recipes; and of

followed in order by milk, wheat, lentils, beans, and maize, which had a biological protein value only one-third of that of good meat. This might account for the pellagrins in certain parts of America and elsewhere if maize was the staple diet. Besides biological value mineral elements were important; too much attention had recently been centred on vitamins, which were no more essential than iodine or soda. The depletion of alkali reserve, which could be restored by mineral matter in organic combination, was responsible for much ill-health, which a more liberal allowance of fruit would cure. E. V. McCollum in a recent book had given three elements of a safe dietary: (1) Milk; (2) small-leaved green vegetables and fruits, for their salts, bases, and vitamins; and (3) offal, of which the biological protein value was much higher than, for example, that of fish. The real essential was not to concentrate on any one aspect of the subject, but to plan a diet bearing in mind energy value, balance, salts, vitamins, and also digestibility and favourable distribution of meals.

Dr. Waller raised for discussion a particular point in the dietetics of young children—viz., the place occupied by cow's milk in the rearing of infants at and shortly after the weaning age. He suggested that if a certain prevalent view is correct, then the baby is unique among young mammals in requiring prolonged milk feeding long after its own mother is capable of the task. For delicate children and for those short of proper nourishment milk is an invaluable remedy. But he held that large numbers of working-class parents, who give their children little or no cow's milk after weaning, show that healthy infants can be reared in this manner. He raised the question for two reasons. The first was that he thought the secret of this type of feeding was worth examining in view of its obvious success. The second was that it differed radically from the manner of feeding commonly prescribed by doctors and nurses for children in the nurseries of the well-to-do—often with an equally obvious lack of success. There might well be a danger that, owing to the growing authority of the infant welfare movement, this tendency to prolonged milk feeding of the young might be too rigidly imposed on the class of parents attending infant clinics with certain disadvantages. He feared a repetition of the unfortunate situation which occurred when two-hourly breast-feeding was widely ordered only to be laboriously cancelled when its drawbacks were appreciated. He wished to emphasise that he referred to children in good health at the normal weaning age, not to invalids or those who could not get food. For these latter types the artisan parent's view that milk is an excellent medicine is correct. But he believed we should keep this medicinal aspect in mind and not lose sight of the fact that an alternative, and biologically a more natural, diet can be framed.

Dr. H. Scurfield, who was elected President of the group for 1923–24, spoke of the varied opinions of well-known pædiatricians on a diet suitable for young children. One considered bananas indigestible, another objected to raw tomatoes and cucumber for children under 7. Dr. Scurfield's own children had all eaten cucumber before they were 2. In contradiction to Dr. Waller's views, McCollum had tried to show that the physique of races who had lived on dairy produce for thousands of years was better than that of others. McCollum's estimate of the amount of milk that should be consumed daily by an adult was a quart; Mellanby suggested a pint. In connexion with vitamins, Dr. Scurfield referred to Dr. W. Cramer's researches,[1] and said that experiments on feeding poultry confirmed his conclusions as to the beneficial results of a diet especially rich in vitamins. The fact that no variation in the composition of human milk was noticeable in tropical climates rather spoilt the theory that milk was adapted to the child's needs under all circumstances; in this case one would expect the fat content to be lessened in hot climates. Dr. Scurfield drew attention to the high temperatures to which milk was subjected in the process of making Devonshire cream, which might be said to be made from pasteurised milk.

Dr. Mabel Brodie drew attention to the fact that in many districts the mothers could not afford to buy cow's milk or dried milk for infants who had been weaned. Many young children could not digest uncooked vegetables, and few were given any meat until between 4 and 5. She asked when normal children should first be given meat.

Dr. Maitland Radford said that the assumption that milk was necessary for young children was of great administrative importance, exemplified by Ministry of Health orders. The Ministry paid half the cost of giving away a considerable amount of milk to expectant and nursing mothers and children under 5. If Dr. Waller's theories were correct, they might do much better with the money.

Dr. H. P. Newsholme asked how mothers were to be instructed. Of recent years research had increasingly emphasised the value of green vegetables and the use of cereals as a main source of diet was being deprecated. The question was not yet decided, however, whether the older method of feeding was practicable in modern times, or even beneficial nowadays. The increase in consumption of cereals by a town population was dependent on their easy carriage, whereas fresh country produce was difficult to convey. Cereals were not ideal foods, but were useful in energy content and could easily be supplemented by "safety" foods.

Dr. C. L. Williams (Todmorden) said that Gowland Hopkins's "Law of the Minimum" had crept into a few text-books, but it was not generally realised how wide were the possible variations in acceptable dietaries. Dogmatism at this stage of our knowledge must be avoided. The essential elements in diet could be bought for a few pence and the rest could be chosen to suit individual taste. For example, there was nothing particularly evil about fish and chips as an article of diet, but when children were given fish and chips only protest must be made.

Dr. Mary Kidd contended that milk could not be dispensed with, and attributed our C 3 population to the tardy effects of under or defective feeding of children. The action of the Ministry of Health in providing milk should not be discouraged, though Dr. Waller's views should be borne in mind.

Dr. E. H. T. Nash (Isleworth) pointed out the difference in nutritive value and digestibility between bananas and plantains.

Dr. Stella Churchill said that since medical men had not interested themselves in the matter of the diet of healthy young children until recent years, much could be learnt by observing the way of tradition. An important point was to give children what they liked to eat. If greens were given early enough children liked them, also meat, chicken, or fish, but they did not as a rule like milk or suet puddings. Tomatoes, cucumbers after the age of 2, and eggs were better than cereals.

Reply.

Dr. Waller pointed out that he did not doubt the enormous value of milk for delicate children. In his opinion statistics showed that it was a mistake to keep children on a fluid diet.

Dr. Pritchard said that he thoroughly agreed with Dr. Newsholme's remarks. One after another cheap food was being discarded or excluded from dietaries because it contained no vitamins; this was ridiculous since vitamins could easily be supplied separately in concentrated form, as in fruit juice, cod-liver oil, and marmite. Separated milk was an excellent foodstuff properly supplemented. The discrediting of Marylebone cream, in spite of its acknowledged energy value, on the count of absence of vitamins appeared to him pure folly. "Get your cheap vitamins somewhere else, but don't condemn good foods" was Dr. Pritchard's concluding message.

Reviews and Notices of Books.

ENCYCLOPÆDIA MEDICA.

Second edition. Vol. IX., Mammillaplasty to Obesity. General Editors, Vols. I.–VIII., the late J. W. BALLANTYNE, M.D., C.M., F.R.C.P.E.; Vol. IX., ALEXANDER GOODALL, M.D., F.R.C.P.E. London and Edinburgh: W. Green and Son, Ltd. 1923. Pp. 672. 30s.

Dr. J. W. Ballantyne, who edited the first eight volumes of the second edition of the Encyclopædia Medica, died in January last, and this regrettable event has, we are informed, delayed the appearance of this volume. The references in many of the articles are, indeed, not to very recent work, though the spirit of most of them is modern. The publishers announce that they were able to secure the editorial services of Dr. Alexander Goodall, for the completion of this and the remaining volumes of the series, of which the publication is expected to be completed next year. Vol. IX. maintains the standard of previous instalments. Notable among those articles revised by the original authors are those on Forensic Medicine, by Prof. Harvey Littlejohn, on Infections of the Nails, by Dr. George Pernet, on Occupation Neuroses, by Dr. Wilfred Harris, and on Acute Inflammations of the Nose, by Mr. Herbert Tilley. It is natural that auto-revision should give the best result, for the introduction of a revising hand, although essential in certain cases, can hardly fail to alter, though perhaps very slightly, the point of view of the original writer. Specially successful, however, is the revision by Dr. C. B. Ker of the section on Epidemic Cerebro-Spinal Meningitis by the late Sir William Osler, and that by Dr. W. A. Potts on Mental Deficiency, written by Dr. G. E. Shuttleworth. New articles are those on Military Surgery, by Sir D'Arcy Power, Mycetoma, by Major W. S. Patton, I.M.S. (ret.), and Neurasthenia, by Dr. Ivy M'Kenzie. We regret that the list of principal articles in the volume, with the names of authors or revisers, is not supplemented by an index of the authors of short articles on subjects of smaller range though by no means necessarily of less importance. Some of these shorter articles, notably one on Masturbation, appear to be most admirable summaries of the subject dealt with, and since the views expressed are not free from controversy, an indication of the name of the author would give confidence to those who hold the same opinions. This is almost the only omission in an admirable volume.

CLINICAL DIAGNOSIS OF INTERNAL DISEASES.

By LLEWELLYS F. BARKER, M.D., LL.D., Professor of Clinical Medicine, Johns Hopkins University. In three volumes. London and New York. D. Appleton and Co. 1923. Pp. 2908. £5.

THESE three volumes originally formed part of a series of six, entitled Monographic Medicine, published in 1916. In a foreword it is stated that they have been republished separately in response to "requests from various quarters." The first feeling produced on looking through the republished volumes is curiosity as to what could have formed the subject-matter of the remainder; for Prof. Barker takes all medical knowledge for his province, even including in his monograph conditions such as ringworm and chronic mastitis, which hardly seem to merit the designation "internal." In an introduction, written in 1916, the author points out that the present-day physician, or "internist" as he prefers to call him, is, or at any rate should be, engaged in "attempting to visualise clearly the functional pathological processes that are the essence of disease." His aim in writing has been to supply information as to methods and procedures available for following these functional pathological processes. This involves the description of the means employed in the investigation of cases in all the fields of medicine, an undertaking of such vast extent that it is amazing that one man should have been found capable of attempting it. That Prof. Barker did attempt it single-handed was due to his belief that "the problems of selection of matter for such a work as the present are such that they can best be met by one man, provided that he has had large clinical experience, some years of laboratory training, and has always been in close touch with clinical workers." Such a man—we had almost said superman—the author would certainly appear to be, and in 1916 the present work must have been nothing short of prodigious. The whole field of diagnosis was covered, so far as it had then been mapped—roentgenology, bacteriology, hæmatology, biochemistry, and biophysics; with all of them the author displayed an equal and astonishing familiarity, and laid before his readers the fruits of the latest work. But that was in 1916, and now it is 1923, and the volumes have apparently been reprinted without further comment, without withdrawal or addition, and with no reference under seven years' old.

Perusal of the work to-day is, in some respects, encouraging. It serves to convince that in spite of cavillers, medicine, so far at any rate as diagnosis is concerned, does move. Prof. Barker's work was in the very forefront of the advancing tide in 1916; in 1923 that tide has flowed far beyond. No doubt it has carried a good deal of worthless flotsam with it, but it has also borne many things of real value. Among these may be mentioned the newer knowledge of the accessory food factors and their relation to the deficiency diseases; the recognition of the curative powers of the actinic rays of sunlight in rickets; the more recent methods of estimating the sugar in the blood, which have made it possible for even the general practitioner with some biochemical training to distinguish true diabetes from the various glycosurias and to follow the condition of his diabetic patients as never before; the simplified urea tests for the gauging of renal functions; the estimation of thyroid overaction or deficiency by observations on the basal metabolism—and the list might be prolonged a good deal further.

It is justifiable to question the wisdom of Prof. Barker in allowing his book to be reprinted even in response to the urgency of its admirers until he or someone else had brought it up to date. It would be unkind further to insist upon the lapses of omission and inclusion incident upon the production in 1923 of a work completed in 1916, and apart from these nothing but matter for admiration remains in Prof. Barker's book. The descriptions of all the well-established clinical methods are excellent. In his zeal for more modern methods the author has not neglected the older modes of investigation, and his description of physical signs of all types and descriptions are masterly. On the main clinical features of every disease he may wish to investigate the practitioner or student could have no better guide than Llewellys Barker.

MEDICAL DIETETICS.

Vorlesungen über Diätbehandlung innerer Krankheiten. Fourth edition. By Prof. H. STRAUSS, Berlin Jewish Hospital. Berlin: S. Karger. 1922. Pp. 471.

Prof. H. Strauss's volume, which has reached a fourth edition, gives in the form of 17 lectures a thoughtful and thorough exposition of the principles which should guide the physician in prescribing food in the commoner diseases. The dietetic treatment of alimentary disorders naturally takes up a good part of the volume. But circulatory and kidney diseases, gout, diabetes, obesity, infectious diseases, and post-operative diets also receive full attention. The tables of analyses at the end are exhaustive and are cast into a useful form, giving the calories, protein, fat, carbohydrate, and water in 100 g. of each food, both raw and as served at the table. Special mention must be made of the valuable appendix of hints for the dietetic kitchen by Elise Hannemann. This contains nearly 100 pages of good recipes; and of

each the composition and the food value are stated. The author rightly asserts that for the dietetic treatment of constipation an exact diagnosis is of first importance. The causes are various; and loss of the power of expulsion is seldom one of them. The delay may be due to atony, to spasm, or to weakness of the abdominal walls, and may be complicated by stenosis, by mucous colitis, or by piles. We notice that the use of X rays to determine the actual nature and seat of the delay is not mentioned. For the spastic forms of constipation a diet calculated to render the motions soft, but poor in cellulose, is advised. It would contain little or no meat, abundance of fruit juices and jellies, honey, whey, buttermilk or sour milk, milk-sugar, lævulose, olive oil, paraffin or agar-agar. For the torpid forms of constipation the usual wholemeal bread, salads, and fruits are recommended. In mucous colitis the cellulose-poor anti-constipation diet is first tried, and later, if needed, a cellulose-rich diet as advocated by v. Noorden.

In speaking of diet in kidney disease Prof. Strauss lays stress on the fact that in many cases of nephritis there is no demonstrable impairment of renal function. There may be a harmless "anephritic" albuminuria. The quantity of albumin is not indeed of value as a guide to the severity of chronic nephritis; neither has diet such a definite influence upon it as was formerly supposed. He doubts also if small quantities of spices and condiments have any adverse effect on the kidney. The reader cannot fail to note Prof. Strauss's practical acquaintance with the phases and consequences of starvation. The copious details offer an arresting contrast to the pre-war literature of a few references to special fasting experiments. We may hope that Europe will see no more of hunger-osteopathy and hunger-œdema. In treating sub-nutrition exercise is valuable. Weak and very thin patients should begin their treatment in bed, but the muscles must be kept in condition by massage, faradisation, and exercises. In the chapter on diabetes the various methods of dieting are discussed in general terms, but few specific instructions, such as the doctor really needs, are given. The analyses of foods are stated in percentages as a rule, though there is one useful table which gives the weights of various foods containing the same quantity of carbohydrate as 10 g. of white bread. A great deal of calculation would be needed to prescribe an accurate diet from these data, much of which can be avoided by the use of tables such as modern English and American text-books on diabetes supply. There is in other chapters also a general tendency to enunciate the principles and to limit the practical application to giving lists of foods to be taken or avoided in the various disorders. The value of these lists would be increased greatly if they were more often supplemented by a detailed account of an actual day's food. The vitamins come in for little attention. Indeed, apart from a discussion of the classical deficiency diseases of scurvy, scurvy-rickets, and beri-beri, the author does not deal with them in detail. He speaks also with caution about the recently expressed view that calcium deficiency is a cause of diseases such as asthma, hay fever, and certain catarrhs.

This is a wise book, a little conservative perhaps, but full of sound experience and knowledge, and free entirely from the dogmatic empiricism which creeps so easily into works on diet.

THE NERVOUS CHILD.

Second edition. By HECTOR CHARLES CAMERON, M.A., M.D., F.R.C.P., Physician in Charge of the Children's Department, Guy's Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 224. 7*s.* 6*d.*

WE like to think that this little book, now appearing in a well-merited second edition, is a product of the English mind and the English spirit. It lies poles asunder from the dreary nastiness of some more ambitious productions emanating from other sources and ostensibly dealing with the mental life of the nervous child. Through its pages runs an illuminating ray of common-sense and medical wisdom which is no less pleasing than instructive. Our children are largely what we make them. In several passages Dr. Cameron rightly lays the emphasis, not on infantile or juvenile experiences per se, but on the attitude of parents and nurses to these. In showing their own apprehensions, and communicating them, they sap the confidence of the child. He declares in no unmeasured terms that for the treatment of childish neuroses psycho-analysis has dangers and produces ill-effects far outweighing any presumable advantages to be gained from it. Management rather than treatment is the keynote of many of his chapters, prevention rather than cure, nursery hygiene rather than specialists' consulting rooms. It is a book to place without reserve in the hand of intelligent parents, governesses, and nurses, no less than in that of the practitioner of medicine; its general tone of optimism is reassuring and cheering; its outlook is sane and healthful, its quiet humour comforting. The insight shown by Dr. Cameron into the mind of the child reveals the profound student of his subject.

DIE LUMBALPUNKTION.

Anatomie, Physiologie, Technik, Untersuchungsmethoden, diagnostische und therapeutische Verwertung. By Dr. MARTIN PAPPENHEIM, Privatdozent in the University of Vienna. Vienna: Rikola Verlag. 1923. Pp. 184.

IN the course of the last ten years a number of text-books dealing with the cerebro-spinal fluid have appeared, but since the subject is one to which research is constantly being devoted, finality has not been reached; new methods come into vogue, new discoveries are announced, new diagnostic procedures are elaborated, with embarrassing frequency. Dr. Martin Pappenheim's brochure represents the very latest advances in all that concerns the fluid. The work is stronger on the chemical than on the microscopical side; Chapter X., on qualitative cell-examination, might be amplified with advantage, and would in any case be improved by drawings of the cell types enumerated. This little book should be in the hands of every laboratory worker, and the clinician will appreciate its usefulness in spite of its admittedly technical character.

LEHRBUCH DER NERVENKRANKHEITEN.

By H. OPPENHEIM. Seventh edition, revised and enlarged, by R. CASSIRER, K. GOLDSTEIN, M. NONNE, and B. PFEIFER, in collaboration. Berlin: S. Karger. 1923. Vol. I. With 323 illustrations and 4 plates. Pp. 923. 27*s.*

GERMAN neurology suffered a grievous loss by the death of Hermann Oppenheim on May 23rd, 1919. It is no mere figure of speech to say that he left behind him a monument of enduring value in his classical text-book, which now appears in a seventh edition, revised and enlarged by four distinguished German neurological confrères. Dr. Cassirer undertook the responsibility of preparing this latest edition, though he says in his preface that with the passing of Oppenheim no single worker could supervise the whole of the field of neurology without help. Hence the collaboration already noted. Oppenheim's book is a treasure-store of neurological knowledge. Scanning its familiar pages again one does not know whether to admire most its comprehensiveness, the skill with which an overwhelming amount of detail is marshalled for assimilation, or the personal touch which runs like a thread through the whole. A cyclopædia of this kind is of permanent importance; it is the outcome of a love of scientific truth which oversteps all national and racial boundaries. We may hope that generations of neurological students who never knew Oppenheim in the flesh will keep his memory green by their appreciation of the best book on the subject that has ever been written.

THEORIES AND PROBLEMS OF CANCER.

By C. E. WALKER, Associate Professor of Cytology in the University of Liverpool. London: University of Liverpool Press and Hodder and Stoughton. 1923. Pp. 126. 5s.

IN this small book the author has brought up to date a series of articles written for Science Progress in 1912. It is addressed to the intelligent layman as well as the more professional public, but we fear that few of the former will be able to understand it, for Prof. Walker fails to realise the width of the gap in thought and terminology which separates him from his neighbour in tram or bus. For the latter it provides a rather gloomy review of those aspects of the cancer problem which have most interested the author. He writes as one wandering hither and thither in a dark forest, not as a happy and adventurous pilgrim who knows that the golden age is just round the corner. It is surely superfluous sadness to belittle the experimental study of transplantable tumours because it has not revealed the cause and cure of cancer and to neglect the great fundamental advances in our knowledge of its nature which have been achieved by this method by the Imperial Cancer Research Fund and others, and which, as far as can be imagined, could have been made by no other means. And it is a simple assumption to say that work in other directions would have been of far greater value. Plenty of people have worked at cancer in other directions and, to say the least, have found out no more. In detail we may note that the criticism (p. 88) of the view that too hot food and drink may cause cancer neglects the mechanism of swallowing as well as the very striking evidence from China connecting the excess of epitheliomas of the lower end of the œsophagus in males with the habit of the women waiting to eat till the men have finished. The statement (p. 52) that *all* the symptoms and damage done by malignant tumours are due to pressure or some other mechanical action on the surrounding parts is hardly in accord with clinical experience of cachexia.

The book contains much that is of interest, and though experienced workers may find but little stimulation in its pages, no thoughtful attempt to unravel such a tangled skein as the cancer problem should be disregarded, and we commend Prof. Walker's book to those who are engaged in working at cancer from whatever aspect.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY. June, 1923. R. Foster Moore: A Watertight Suture in Trephining. It is generally acknowledged that the localised cystic swelling sometimes seen after trephining is undesirable, and that the result to aim at is a more diffuse subconjunctival œdema, showing that the excess fluid from the globe has free drainage into the subconjunctival space. To obtain this desirable result Foster Moore completes his operation by carefully suturing the edges of his conjunctival incision, thus preventing the sealing down of the lateral parts of the conjunctival flap which takes place if the fluid is allowed from the first to find an exit through an unsutured conjunctival incision.—The late Charles Killick: Treatment of Conical Cornea. Finding the recognised methods of surgical treatment unsatisfactory, Killick has had recourse to a simple extraction of the lens with a subsequent needling operation to form a vertical slit in the capsule. By this means he succeeded in improving the vision of one patient from less than 6/60 to 6/24. As a conical cornea necessarily causes high myopia it is perhaps surprising that this procedure has not been tried before.—R. P. Ratnaker: Blue Cataract. The blue dots sometimes seen in the lens by focal illumination do not interfere with vision very much, and they seldom progress into a condition calling for operation. It therefore seems a pity to use the word cataract. The author suggests that some other word, less alarming to the patient, should be found for all non-progressive opacities of the lens.—C. H. Bryant: The Third Dimension in Monocular Vision. Stereoscopic vision is popularly supposed to be impossible with one eye. Bryant suggests that it is attained by the unconscious comparison of the image which falls in the [macula with the more or less blurred images of objects not in the direct line of vision, and this theory seems altogether probable. "An experimental proof of this is readily made by viewing the landscape through a series of opaque tubes of increasing calibre. In proportion as the field viewed is made more extensive and more objects are seen in it, so does the sense of depth become more evident."

JOURNAL OF INDUSTRIAL HYGIENE. May and June, 1923.—In the May issue D. A. Coles contributes a short but useful article on how to report an industrial accident which may result in a compensation claim. First there must be proof that an accident has occurred. Next the present condition, including parts of the body not involved in the accident, should be accurately noted. Then a statement should follow of incapacity caused and prognosis of its temporary or permanent character. If the doctor is immediately on the spot, a plan of the scene of the accident with measurements should be made, and evidence of those present should be taken. Legal proceedings would often be simplified if doctors would *remember they* may have to become witnesses, which they *usually* forget while attending to the injured person.—The causation of industrial accidents is dealt with by H. M. Vernon, who, as the result of extensive investigation, concludes that fatigue may cause a moderate increase of accident-frequency when the hours of work are very long; but that *during* the course of ordinary work-spells fatigue has little to do with any increase of accidents, which is chiefly due to variations in speed of production and the psychical state of the workers. He found accident-frequency at a minimum at 67° F., increasing rapidly at lower and higher temperatures; thus it was 35 per cent. greater at 52° and 23 per cent. greater at 77° than at 67° F.—An important paper by P. Drinker, R. M. Thompson, and S. M. Fitchet, dealing with atmospheric particulate matter begins in May and is completed in the June issue. The authors give an excellent summary of previous work on the subject, although Owens's new jet counter was apparently too recent to be considered. The errors which are involved in various methods used to determine the dust present in air are pointed out. The authors then describe a new apparatus for which high efficiency is claimed. Dusty air is passed through water at 8 to 10 cubic feet per minute: entrainment losses are avoided by spiralling the exhaust air out of the collector and thus changing its direction; a vacuum cleaner motor-fan, which is equipped with a rheostat for speed control, serves as the source of suction; while an orifice meter at the exhaust measures air-flow.—In the June issue H. C. Weston reports an investigation into the efficiency of linen-weavers, which was found to vary directly with wet-bulb temperature; but after 73° F. was reached efficiency fell as the wet-bulb temperature rose. As a working maximum a wet-bulb temperature of 70° F. is suggested to ensure maximum production consistent with health and comfort. Efficiency under artificial light fell below its daylight value by 11 per cent.; to avoid this fall good general as well as local illumination is required. Reasonable reduction in hours of work appear to favour the production of a uniform work-curve without a proportional reduction in *total output*.—M. C. Sturgis, after inquiring into the effect *of* dysmenorrhœa among working women, concludes that *the* great majority of women suffer no appreciable loss of efficiency during the menstrual function; 65 per cent. experi*enced no* handicap, 30·6 per cent. only slight handicap, but 4·4 per cent. were seriously affected. Methods for overcoming any lowered efficiency are put forward.

each the composition and the food value are stated. The author rightly asserts that for the dietetic treatment of constipation an exact diagnosis is of first importance. The causes are various; and loss of the power of expulsion is seldom one of them. The delay may be due to atony, to spasm, or to weakness of the abdominal walls, and may be complicated by stenosis, by mucous colitis, or by piles. We notice that the use of X rays to determine the actual nature and seat of the delay is not mentioned. For the spastic forms of constipation a diet calculated to render the motions soft, but poor in cellulose, is advised. It would contain little or no meat, abundance of fruit juices and jellies, honey, whey, buttermilk or sour milk, milk-sugar, lævulose, olive oil, paraffin or agar-agar. For the torpid forms of constipation the usual wholemeal bread, salads, and fruits are recommended. In mucous colitis the cellulose-poor anti-constipation diet is first tried, and later, if needed, a cellulose-rich diet as advocated by v. Noorden.

In speaking of diet in kidney disease Prof. Strauss lays stress on the fact that in many cases of nephritis there is no demonstrable impairment of renal function. There may be a harmless "anephritic" albuminuria. The quantity of albumin is not indeed of value as a guide to the severity of chronic nephritis; neither has diet such a definite influence upon it as was formerly supposed. He doubts also if small quantities of spices and condiments have any adverse effect on the kidney. The reader cannot fail to note Prof. Strauss's practical acquaintance with the phases and consequences of starvation. The copious details offer an arresting contrast to the pre-war literature of a few references to special fasting experiments. We may hope that Europe will see no more of hunger-osteopathy and hunger-œdema. In treating sub-nutrition exercise is valuable. Weak and very thin patients should begin their treatment in bed, but the muscles must be kept in condition by massage, faradisation, and exercises. In the chapter on diabetes the various methods of dieting are discussed in general terms, but few specific instructions, such as the doctor really needs, are given. The analyses of foods are stated in percentages as a rule, though there is one useful table which gives the weights of various foods containing the same quantity of carbohydrate as 10 g. of white bread. A great deal of calculation would be needed to prescribe an accurate diet from these data, much of which can be avoided by the use of tables such as modern English and American text-books on diabetes supply. There is in other chapters also a general tendency to enunciate the principles and to limit the practical application to giving lists of foods to be taken or avoided in the various disorders. The value of these lists would be increased greatly if they were more often supplemented by a detailed account of an actual day's food. The vitamins come in for little attention. Indeed, apart from a discussion of the classical deficiency diseases of scurvy, scurvy-rickets, and beri-beri, the author does not deal with them in detail. He speaks also with caution about the recently expressed view that calcium deficiency is a cause of diseases such as asthma, hay fever, and certain catarrhs.

This is a wise book, a little conservative perhaps, but full of sound experience and knowledge, and free entirely from the dogmatic empiricism which creeps so easily into works on diet.

THE NERVOUS CHILD.

Second edition. By HECTOR CHARLES CAMERON, M.A., M.D., F.R.C.P., Physician in Charge of the Children's Department, Guy's Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 224. 7*s.* 6*d.*

WE like to think that this little book, now appearing in a well-merited second edition, is a product of the English mind and the English spirit. It lies poles asunder from the dreary nastiness of some more ambitious productions emanating from other sources and ostensibly dealing with the mental life of the nervous child. Through its pages runs an illuminating ray of common-sense and medical wisdom which is no less pleasing than instructive. Our children are largely what we make them. In several passages Dr. Cameron rightly lays the emphasis, not on infantile or juvenile experiences per se, but on the attitude of parents and nurses to these. In showing their own apprehensions, and communicating them, they sap the confidence of the child. He declares in no unmeasured terms that for the treatment of childish neuroses psycho-analysis has dangers and produces ill-effects far outweighing any presumable advantages to be gained from it. Management rather than treatment is the keynote of many of his chapters, prevention rather than cure, nursery hygiene rather than specialists' consulting rooms. It is a book to place without reserve in the hand of intelligent parents, governesses, and nurses, no less than in that of the practitioner of medicine; its general tone of optimism is reassuring and cheering; its outlook is sane and healthful, its quiet humour comforting. The insight shown by Dr. Cameron into the mind of the child reveals the profound student of his subject.

DIE LUMBALPUNKTION.

Anatomie, Physiologie, Technik, Untersuchungsmethoden, diagnostische und therapeutische Verwertung. By Dr. MARTIN PAPPENHEIM, Privatdozent in the University of Vienna. Vienna: Rikola Verlag. 1923. Pp. 184.

IN the course of the last ten years a number of text-books dealing with the cerebro-spinal fluid have appeared, but since the subject is one to which research is constantly being devoted, finality has not been reached; new methods come into vogue, new discoveries are announced, new diagnostic procedures are elaborated, with embarrassing frequency. Dr. Martin Pappenheim's brochure represents the very latest advances in all that concerns the fluid. The work is stronger on the chemical than on the microscopical side; Chapter X., on qualitative cell-examination, might be amplified with advantage, and would in any case be improved by drawings of the cell types enumerated. This little book should be in the hands of every laboratory worker, and the clinician will appreciate its usefulness in spite of its admittedly technical character.

LEHRBUCH DER NERVENKRANKHEITEN.

By H. OPPENHEIM. Seventh edition, revised and enlarged, by R. CASSIRER, K. GOLDSTEIN, M. NONNE, and B. PFEIFER, in collaboration. *Berlin: S. Karger. 1923. Vol. I. With 323 illustrations and 4 plates. Pp.* 923. 27*s.*

GERMAN neurology suffered a grievous loss by the death of Hermann Oppenheim on May 23rd, 1919. It is no mere figure of speech to say that he left behind him a monument of enduring value in his classical text-book, which now appears in a seventh edition, revised and enlarged by four distinguished German neurological confrères. Dr. Cassirer undertook the responsibility of preparing this latest edition, though he says in his preface that with the passing of Oppenheim no single worker could supervise the whole of the field of neurology without help. Hence the collaboration already noted. Oppenheim's book is a treasure-store of neurological knowledge. Scanning its familiar pages again one does not know whether to admire most its comprehensiveness, the skill with which an overwhelming amount of detail is marshalled for assimilation, or the personal touch which runs like a thread through the whole. A cyclopædia of this kind is of permanent importance; it is the outcome of a love of scientific truth which oversteps all national and racial boundaries. We may hope that generations of neurological students who never knew Oppenheim in the flesh will keep his memory green by their appreciation of the best book on the subject that has ever been written.

THEORIES AND PROBLEMS OF CANCER.

By C. E. WALKER, Associate Professor of Cytology in the University of Liverpool. London: University of Liverpool Press and Hodder and Stoughton. 1923. Pp. 126. 5s.

IN this small book the author has brought up to date a series of articles written for Science Progress in 1912. It is addressed to the intelligent layman as well as the more professional public, but we fear that few of the former will be able to understand it, for Prof. Walker fails to realise the width of the gap in thought and terminology which separates him from his neighbour in tram or bus. For the latter it provides a rather gloomy review of those aspects of the cancer problem which have most interested the author. He writes as one wandering hither and thither in a dark forest, not as a happy and adventurous pilgrim who knows that the golden age is just round the corner. It is surely superfluous sadness to belittle the experimental study of transplantable tumours because it has not revealed the cause and cure of cancer and to neglect the great fundamental advances in our knowledge of its nature which have been achieved by this method by the Imperial Cancer Research Fund and others, and which, as far as can be imagined, could have been made by no other means. And it is a simple assumption to say that work in other directions would have been of far greater value. Plenty of people have worked at cancer in other directions and, to say the least, have found out no more. In detail we may note that the criticism (p. 88) of the view that too hot food and drink may cause cancer neglects the mechanism of swallowing as well as the very striking evidence from China connecting the excess of epitheliomas of the lower end of the œsophagus in males with the habit of the women waiting to eat till the men have finished. The statement (p. 52) that all the symptoms and damage done by malignant tumours are due to pressure or some other mechanical action on the surrounding parts is hardly in accord with clinical experience of cachexia.

The book contains much that is of interest, and though experienced workers may find but little stimulation in its pages, no thoughtful attempt to unravel such a tangled skein as the cancer problem should be disregarded, and we commend Prof. Walker's book to those who are engaged in working at cancer from whatever aspect.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY. *June*, 1923. *R. Foster Moore*: A Watertight Suture in Trephining. It is generally acknowledged that the localised cystic swelling sometimes seen after trephining is undesirable, and that the result to aim at is a more diffuse subconjunctival œdema, *showing that the excess fluid* from the globe has free drainage into the subconjunctival space. To obtain this desirable result Foster Moore completes his operation by carefully suturing the edges of his conjunctival incision, thus preventing the sealing down of the lateral parts of the conjunctival flap which takes place if the fluid is allowed from the first to find an exit through an unsutured conjunctival incision.—The late Charles Killick: Treatment of Conical Cornea. Finding the recognised methods of surgical treatment unsatisfactory, Killick has had recourse to a simple extraction of the lens with a subsequent needling operation to form a vertical slit in the capsule. By this means he succeeded in improving the vision of one patient from less than 6/60 to 6/24. As a conical cornea necessarily causes high myopia it is perhaps surprising that this procedure has not been tried before.—R. P. Ratnaker: Blue Cataract. The blue dots sometimes seen in the lens by focal illumination do not interfere with vision very much, and they seldom progress into a condition calling for operation. It therefore seems a pity to use the word cataract. The author suggests that some other word, less alarming to the patient, should be found for all non-progressive opacities of the lens.—C. H. Bryant: The Third Dimension in Monocular Vision. Stereoscopic vision is popularly supposed to be impossible with one eye. Bryant suggests that it is attained by the unconscious comparison of the image which falls in the macula with the more or less blurred images of objects not in the direct line of vision, and this theory seems altogether probable. "An experimental proof of this is readily made by viewing the landscape through a series of opaque tubes of increasing calibre. In proportion as the field viewed is made more extensive and more objects are seen in it, so does the sense of depth become more evident."

JOURNAL OF INDUSTRIAL HYGIENE. May and June, 1923.—In the May issue D. A. Coles contributes a short but useful article on how to report an industrial accident which may result in a compensation claim. First there must be proof that an accident has occurred. Next the present condition, including parts of the body not involved in the accident, should be accurately noted. Then a statement should follow of incapacity caused and prognosis of its temporary or permanent character. If the doctor is immediately on the spot, a plan of the scene of the accident with measurements should be made, and evidence of those present should be taken. Legal proceedings would often be simplified if doctors would remember they may have to become witnesses, which they usually forget while attending to the injured person.—The causation of industrial accidents is dealt with by H. M. Vernon, who, as the result of extensive investigation, concludes that fatigue may cause a moderate increase of accident-frequency when the hours of work are very long; but that during the course of ordinary work-spells fatigue has little to do with any increase of accidents, which is chiefly due to variations in speed of production and the psychical state of the workers. He found accident-frequency at a minimum at 67° F., increasing rapidly at lower and higher temperatures; thus it was 35 per cent. greater at 52° and 23 per cent. greater at 77° than at 67° F.—An important paper by P. Drinker, R. M. Thompson, and S. M. Fitchet, dealing with atmospheric particulate matter begins in May and is completed in the June issue. The authors give an excellent summary of previous work on the subject, although Owens's new jet counter was apparently too recent to be considered. The errors which are involved in various methods used to determine the dust present in air are pointed out. The authors then describe a new apparatus for which high efficiency is claimed. Dusty air is passed through water at 8 to 10 cubic feet per minute; entrainment losses are avoided by spiralling the exhaust air out of the collector and thus changing its direction; a vacuum cleaner motor-fan, which is equipped with a rheostat for speed control, serves as the source of suction; while an orifice meter at the exhaust measures air-flow.—In the June issue H. C. Weston reports an investigation into the efficiency of linen-weavers, which was found to vary directly with wet-bulb temperature; but after 73° F. was reached efficiency fell as the wet-bulb temperature rose. As a working maximum a wet-bulb temperature of 70° F. is suggested to ensure maximum production consistent with health and comfort. Efficiency under artificial light fell below its daylight value by 11 per cent.; to avoid this fall good general as well as local illumination is required. Reasonable reduction in hours of work appear to favour the production of a uniform work-curve without a proportional reduction in total output.—M. C. Sturgis, after inquiring into the effect of dysmenorrhœa among working women, concludes that the great majority of women suffer no appreciable loss of efficiency during the menstrual function; 65 per cent. experienced no handicap, 30·6 per cent. only slight handicap, but 4·4 per cent. were seriously affected. Methods for overcoming any lowered efficiency are put forward.

MENTAL HOSPITALS SERVICE.

TWO SCOTTISH HOSPITALS.

IN the annual report for 1922 of the *Glengall Hospital for Mental Diseases, Ayr,* the medical superintendent, Dr. G. Douglas McCrae, protests against the delay which occurs in committing patients to mental hospitals for treatment. Excluding congenital cases, 61 per cent. of the men and 48 per cent. of the women had exhibited symptoms of mental disease for more than a year before being sent to this hospital for treatment—in the case of one woman three years, in another 12 years, and in a third 20 years, had elapsed. Scarcely 9 per cent. of the men and only 16 per cent. of the women were admitted within three months of the onset of the mental illness. With regard to physical health, the proportion of cases seriously exhausted on admission was unusually high at 45 per cent. among the men and 50 per cent. among the women; this index of the hospital nature of the institution ought to appeal to all but the indifferent and unconvincible among the general public. Dr. McCrae regards some of the stereotyped predisposing causes of insanity with a respect which is tempered with some amusement. "Among the causes of the mental illness in those admitted, hereditary predisposition was acknowledged in 30 per cent., as usual. While it may be correct to affirm that no man can become insane unless he be constitutionally 'nervous,' who can truthfully assume, however confidently he may assert, that no case of mental disease has ever occurred among his ancestors? Not even the brain in the Piltdown skull could claim such immunity." "Notwithstanding that the incidence of alcohol is steadily decreasing, a high annual admission-rate is maintained. It is not alcohol that fills the asylums, but it does serve to indicate those who ought to be in the asylum, where the alcoholic degenerate is a *rara avis*, though a well-recognised species amongst the general community." A remarkable item in the statistics is the supply, from the gardens, of 1084¼ lb. of parsley in one year to an institution providing food for not more than 600 people.

The annual report for 1922 of the *Glasgow Royal Asylum* records the acquisition of two new buildings, one of which is being used as a nursing home for incipient cases, and one, which occupies an attractive position overlooking the Firth of Clyde, as a convalescent and holiday home for patients in the hospital. It is also hoped to build a new nurses' home in the near future. An original step has been taken in appointing an instructor in occupational therapy; this is said to be the first example of such an appointment in a hospital of this kind in Scotland. Among the subjects on which research work is in progress are the part played by focal infections in insanity, the blood-sugar content in states of depression associated with anxiety, and the effect of spinal drainage, reinforced by giving mercury and arsenic, in organic disease of the nervous system (exact particulars of this work are not given). The medical superintendent's report embraces a discussion of the part played by alcoholism in the production of insanity. "My general feeling is," writes Dr. D. K. Henderson, "that alcohol as a cause of mental disorder is of great importance, but very frequently also it is merely a symptom, and points the way to a more definite and profound underlying cause. Under these circumstances I think that purely prohibitive measures will never succeed, because the question is not so simple as to be dealt with in such a crude way." The only satisfactory solution, he concludes, is to attempt to produce better conditions of life, and to study the individual and environmental conditions which are at the bottom of this habit disorder.

TWO PRIVATE MENTAL HOSPITALS.

In the annual report of *The Retreat, York,* Dr. Henry Yellowlees, who has succeeded Dr. Bedford Pierce as medical superintendent, maintains a tradition common to several such institutions in contributing a long and very readable superintendent's report, dealing with a number of questions of general interest. Similar points are raised by Dr. Arthur Townsend in the annual report of *Barnwood House, Gloucester.* A remarkable feature of the year's work at The Retreat was the high proportion of voluntary boarders admitted, no less than 46 per cent. of the total number of patients. The proportion at Barnwood House was much smaller, and Dr. Townsend deplores the difficulty of widening the scope of the voluntary status. He cites the example of a voluntary boarder whose condition for the time being became such that, by the present standards, certification was inevitable. Within a fortnight she was well. The problem of providing occupation for the patients is another subject which is engaging the attention of the authorities at both of these hospitals. Games and gardening have always figured largely at The Retreat, and a new social venture is represented in "Harbour Lights," a magazine edited and very largely written by the patients. There is room, however, for more work of a different nature, the whole being systematised under the control of an officer whose time is devoted solely to this purpose. This is the end in view in each case, and Dr. Townsend suggests the possibility of "classes of instruction" in various arts and handicrafts.

At Barnwood House there is some prospect that the nurses may be engaged under stricter form of agreement. In spite of good conditions and relatively high payment, a number have been leaving before their course of instruction has been completed. It is desirable that mental nursing as a career should be brought more generally to the notice of the public; the difficulty experienced in staffing mental hospitals is due chiefly to ignorance, either of the nature of work, or of its mere existence as a career. "It seems strange that while so much is done for the nursing of the sick, so few should be willing to devote themselves to the care of the insane, which is the highest and most difficult of all nursing. . . . To do it well requires high qualities of head and heart; and there can be no better or worthier sphere for those whose desire it is not merely to gain a living, but to be at the same time 'continually doing good.'" This quotation, reproduced by Dr. Yellowlees, is from an annual report for 1875. In his words "it is even more fully true to-day than when it was written almost 50 years ago."

New Inventions.

A MANDIBLE RETRACTOR.

THE accompanying illustration shows an instrument devised during the war for pulling the mandible forward under an anæsthetic. This retractor has proved to be of value during anæsthesia under conditions of impeded respiration, and where it is necessary to advance the mandible. In the first instance the instrument was devised for cases in which the mandible had been fractured and originally it was made from iron wire. It has now been in use for some years, and has proved so useful that others may be glad to avail themselves of the pattern made from it by the Surgical Manufacturing Co., Ltd., Mortimer-street, London, W. 1.

THE LANCET.

LONDON: SATURDAY, JULY 14, 1923.

SMALL-POX AND VACCINATION.

We printed in the last issue of The Lancet the official figures giving the notifications of small-pox for the preceding week in England and Wales; those of the following week, bringing the account up to June 30th, have now been published, and are quoted in a statement with regard to the small-pox situation which has been issued from the Ministry of Health and appears on p. 92. This statement dwells in the first instance on the failure at Gloucester to control the disease when control would have been easy. There were cases of small-pox in the city as far back as April, and official warning was received from the Ministry of Health by the sanitary authority early in May that in other cases occurring in distant localities the source of infection had been traced to Gloucester; but notification by local practitioners was refused by the medical officer of health, in the view, presumably, that the diagnosis was in error. The question as to whether the disease was in fact small-pox was finally settled by expert advice, both official and other, when the local authority was immediately assisted, under the superintendence of Dr. W. H. Davison, senior assistant to the medical officer of health at Birmingham, to set up a special hospital and special vaccinating stations, to trace contacts, and to do everything possible to stamp out the infection locally, and to prevent its further spread.

The statement from the Ministry of Health, which includes figures proving that the incidence of small-pox is at present widely spread in the country, is uncompromising in its recommendation of vaccination as the only practical remedy now that the infection has been introduced. No one denies that the decline of small-pox, as of most epidemic diseases, is influenced by a rise in the standard of the sanitary conditions and the economic opportunities of the population, but no serious student of epidemiology can doubt that in vaccination we have a practical method of controlling further spread of this disease when an outbreak has occurred. The value of universal compulsory vaccination and revaccination would be well worth discussing in the light of all the information now available and outside the murky atmosphere of dialectics. For the moment it is happily an academic question for the greater part of the country, and even admitting that the influence of vaccination is neither individually infallible nor permanent, this need not impart a hesitating quality into our advocacy of the procedure in face of a local outbreak of disease. The outcome of the frank views of the Ministry of Health is believed in some quarters to be the prelude to amendment in the law, but Mr. Neville Chamberlain has expressed his belief that no special legislation is necessary.

OPERATIONS FOR DISEASE OF THE GALL-BLADDER.

The surgery of the biliary tract is passing through the stages which have characterised the evolution of surgery of other abdominal organs. The perfecting of technique by specialist operators has shown the general practitioner how, in case of need, intervention in gall-stone disease may be undertaken with a moderate assurance of an immediate happy outcome. The result is that, rather prematurely perhaps, this branch of surgery is being practised by a large number of men, before knowledge has become sufficiently exact to indicate in all cases the proper course to follow. It is pertinent, too, to remember that the available and reliable statistics are those of the most experienced surgeons who, in their writings, characteristically fail to lay stress upon that perfection of technique which has done so much to furthering their favourable results. For these operators, biliary surgery has passed beyond the stage of developing a technique of intervention to that of deciding what procedure will best meet the existing pathological and physiological processes at work in each particular patient, so that, amongst them, controversy centres round the advisability of cholecystectomy or cholecystostomy, when gall-stones exist without complications. There seems to be a growing conviction amongst operators of experience, not only in this country, that the end-results of cholecystectomy are very much better than those of the simpler cholecystostomy. At a recent meeting of the Royal Society of Medicine, where the surgery of the common bile-duct was under discussion, Mr. James Sherren emphatically declared that "when the correct treatment for disease of the gall-bladder is carried out," meaning cholecystectomy, "we shall cease to have to discuss and carry out operations for the removal of duct calculi." In other words, his experience has led him to the conclusion that the recognition of early cholecystitis should be followed by removal of the gall-bladder.

Cholecystectomy is, indeed, being very widely practised just now. It must be accepted as a fact that a large percentage of favourable results ensue when they are vouched for by the leaders of gall-bladder surgery, but it is relevant to ask whether we have not travelled too far in this direction; whether, with a more careful selection, certain gall-bladders which are now sacrificed might not be preserved to play their part in the physiological economy of the individual. The fact that patients from whom the gall-bladder has been removed show few signs of being different from normal people, demonstrates no more than the marvellous powers of adaptation the body possesses, for there is abundant evidence that the organ has very important functions to perform. After the gall-bladder has been removed, either there is a varying but constant flow of bile *into* the duodenum, or, should the sphincter of Oddi remain continent, a dilatation of the bile-ducts behind it, in order to accommodate the dilute bile which is no longer reduced to one-tenth of its volume by gall-bladder activity. In either case the physiology of digestion is disturbed. Achylia occurs in 47 *per cent.* of cases of gall-stones.[1] In dogs cholecystectomy gives rise to achylia. It has also been found associated with a stone impacted in the cystic duct, which suggests that it is due to loss of gall-bladder function. Some observers, on the other hand, have demonstrated that in man the gastric juice may show normal acidity after removal of the

questions of fact which matter to the practitioner in an inquiry under Part VI. No doubt when the procedure of an inquiry under the National Health Insurance Acts was being assimilated to the procedure of arbitration under the 1887 Act, the object constantly before the minds of those who were devising procedure was that of getting decisions of fact without going to court. Neither Parliament nor the judicial bench are likely to encourage the re-trial of matters of fact already decided by some other tribunal. It is one thing to keep a lay tribunal straight on points of law, it is quite another thing to interfere with it on points of fact.

REWARD FOR MEDICAL DISCOVERY.

THE propriety of monetary recompense for scientific discoveries has been talked and written about for years without any clear outcome. The real issue is the difficulty of reconciling the two aspects, economical and ethical, of the problem. These two considerations are often in sharp and unexpected conflict, while both must be taken into account. Accepting the position outlined in a recent discussion on Prof. DREYER'S work, that even the most startling discovery in modern medicine can be no more than a link in a chain already forged, the element of chance in any individual piece of work proving to be that link is very large. When fame alone is to be the reward, merit is difficult enough to assess; if it be known that fortune also is at stake, heartburnings, struggles, and even those personal vituperations which have, to the honour of medicine, declined so greatly of recent years, may reappear. Even if the general principle is conceded that on ethical grounds that which proves of public service should be rewarded, the solution of the problem is not complete. Should the reward be a free gift, or should it be that form of gratitude which has an eye on favours still to come? We announced last week that the Canadian Parliament had unanimously voted an annuity of $7500 (£1500) to Dr. BANTING, the discoverer of insulin, to enable him to carry on his scientific work—or, as one lay paper phrased it, "to devote his life to medical research." It is the interpretation to be placed on this intriguing phrase, quite independent of its immediate context or of the personal problems of the present most worthy recipient, that we propose to investigate.

It is difficult to believe that this example of the Canadian Government will not be followed, and it therefore appears important to arrive at definite principles which govern such rewards, for they mark a distinct stage in the stimulation and encouragement of medical research. It should be settled first of all whether such grants are to be additional to any salary which the recipient would enjoy in the ordinary course of events. If not, they really represent institutional or university subsidies, and the way becomes open for intrigues among corporate bodies, with possible injustice to individuals; if, on the other hand, they are additional, then steps must be taken to ensure against the possible economic injustices inherent in subsidised labour. Again, are the grants to be given for actual or potential achievements? If for actual achievements, as already indicated great difficulties would seem to emerge. The placing of the coping-stone may be the least difficult part of the erection of a building, and how shall adjudication be made among the many labourers who have contributed to the whole? It must be remembered that the greatest discoveries may fail to receive contemporary recognition. Second-rate work is always more easily recognised by the majority, who themselves are and must be second-rate, and scarcely capable of recognising and immediately appreciating the enduring first-rate. Thus either injustice may be done or a reward may be delayed till it is no longer of use. If, on the other hand, grants are given for potential achievements, what provision will be made to ensure that the worker has facilities for carrying out his work? The ablest men are not always the most congenial colleagues, and we can conceive of a situation arising in which the recipient of such a reward may find it difficult to secure facilities. It must be remembered, also, that while few men achieve one great thing in life, far fewer achieve more than one. Is the recipient to have perfect freedom to elaborate for the rest of his life the details of his discovery—supposing that the same individual is temperamentally capable of such different forms of labour, or must he be for ever striving to produce a second discovery—a dangerous practice, for this way lie prematurity and disillusionment. May he forsake, for example, laboratory work and take up clinical practice, or is he to be tied to the one or the other? To the best type of man more than purely nominal control must be undignified and degrading, yet will nations or public bodies be prepared to support a worker indefinitely, without the periodical report or blue-book? Are they prepared to recognise that having chosen their man they must for ever after trust him and hold their peace, when the first flush of enthusiasm over his initial discovery has faded? The inevitable conclusion is that they must, if the tribute is not to be a yoke rather than a wreath.

To return to the particular instance which inspired this consideration of the broad issues involved, we may regard the rider appended by the Canadian Government to their gift as no more than a graceful recognition of the manner in which the man they have honoured will choose to live his life. This is in substantial accordance with the views of the joint committee representing the British Medical Association and the British Science Guild, whose report on the need for rewards for medical discovery was published in THE LANCET of Jan. 10th, 1920. Their proposals were: (1) That Parliament should resuscitate the precedent of JENNER by paying *compensation* when due for losses incurred in achieving medical discoveries; (2) that Parliament should provide an annual sum, say of not less than £20,000, for life pensions to be given as rewards to such of His Majesty's subjects as have made worthy medical discoveries, such pensions amounting to between £500 and £1000 a year. The Committee add that such pensions would be preferable to donations in capital, and the sums suggested would be sufficient, because men of science seek only such independence as will enable them to employ their talents in the manner they think best. The difficulties which we have set out above were appreciated by Earl BALFOUR, who as Lord President of the Council, received a deputation from the Medical Committee of the House of Commons in support of these recommendations. He received the proposals sympathetically, but held that a better plan would be to place investigators in a more comfortable position for carrying out their research work.[1] The two schemes are not incompatible, and indeed every important discovery made has a secondary value in enhancing the prestige and the claims for a living wage of those engaged in disentangling the intricate problems of medical science.

INDEX TO "THE LANCET," VOL. I., 1923.

THE Index and Title-page to Vol. I., 1923, which was completed with the issue of June 30th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

gall-bladder. How can these results be explained? Very possibly they depend upon the behaviour of the sphincter of Oddi, which cannot be predicted. If it remains functional, so that the flow of bile into the intestine is intermittent, then gastric secretion may take place as usual, but should a continuous flow of bile occur, then secretion of the pancreatic and gastric juices is much diminished. The digestive disturbances after cholecystectomy, which are familiar to surgeons of experience and recognised as occurring in a certain proportion of cases, are probably due much more to these causes than to the adhesions which are blamed, but are often not found on re-exploration. If the sphincter of Oddi remains continent after cholecystectomy, the greatly increased pressure against which the liver has to secrete leads to dilatation of the common and intrahepatic ducts, and must surely be disadvantageous to this organ in the long run, just as the kidneys cannot indefinitely secrete against pressure without harm coming to them. When it is remembered that the liver is the largest gland in the body, that it is the great metabolic laboratory of the organism, this consideration cannot lightly be set aside.

A powerful argument in favour of cholecystectomy is the view that the gall-bladder is the place of origin of the majority of gall-stones. Doubt has been thrown upon this belief by Aufrecht,[2] who states that in atrophic cirrhosis, in the neighbourhood of carcinomatous nodules, and when damming back of bile has occurred during pregnancy, liver-sand is often found in the smaller bile-ducts. The relief of pressure at parturition allows a free flow of bile again, and the discharge of the sand down the ducts is the cause of the biliary colic seen after child-birth. This observer believes that gall-stones arise in the liver and grow in the gall-bladder, so that the removal of the gall-bladder does not necessarily mean the extinction of the focus of origin of gall-stones. E. A. Graham[3] established the constant association of hepatitis with cholecystitis, and the work of M. G. Peterman[4] has demonstrated what the connexion is. He found that if streptococci were injected into the portal vein they could be detected in the wall of the gall-bladder and in the substance of the liver, although the cystic duct and artery had been previously ligated, and that they only appeared in the gall-bladder wall subsequently to their appearance in the liver. Infection took place by connecting lymphatics. It is true also that in early cholecystitis the outer layers of the wall of the gall-bladder are more affected than the mucosa. It therefore seems to follow that the origin of cholecystitis is really in the liver substance. This does not mean that cholecystectomy is a fundamentally wrong operation. It may quite well be that infection in the liver tends towards cure of itself, whilst restitution of the gall-bladder walls to normal is difficult of achievement.

In the light of such recent work, the after-history of patients who have been submitted to cholecystectomy requires careful reinvestigation, with a view to making a true comparison with patients submitted to cholecystostomy, where the gall-bladder appeared at operation to be capable of recovery. Although the mortality of cholecystectomy has been much reduced by modern methods, it remains a more serious operation than cholecystostomy, so that an attempt to restrict its field of application is desirable. To remove a gall-bladder is a confession of failure to attain the ideals of surgery in this region of the body—namely, a restoration to normal function, although it seems from present available evidence to be unusually effective in bringing relief to a large proportion of sufferers.

◆

THE PRACTITIONER'S RIGHT OF APPEAL.

Last month we received from the Welsh Board of Health a formal notice that after an inquiry, held in accordance with Part VI. of the Medical Benefit Consolidated Regulations for 1923, the name of a qualified and registered practitioner had been removed from the medical list for the county of Glamorgan. Similar notices reach us from time to time from the Ministry of Health. Four years ago, at one of the annual conferences of local medical and panel committees a resolution was passed to the effect that no medical practitioner should be deprived of the right to continue in insurance practice without the liberty of appeal to an independent judicial administrative body or court other than H.M. Insurance Commissioners or the Ministry of Health. Dr. J. H. Clements, who recalls this resolution in our correspondence columns, regards the negotiating body as having been lax in allowing the new agreement for service to go through without establishing this principle of the right of appeal or, as he himself would perhaps more vigorously put it—though this issue is a secondary one for our present purpose—as having claimed the victory whereas they had sold the pass.

The complete facts are not very easy to come by, but the position apparently is, that there is no appeal to the law courts for a practitioner whose name is being taken off the list as a result of such an inquiry as we have alluded to, although under Section 7 of the Nurses Registration Act of 1919 a nurse threatened with having her name removed from the Nursing Register may appeal to the High Court; under Section 9 of the Dentists Act of 1921 a dentist has a similar right of appeal, and under Section 4 of the Midwives Act of 1902 a midwife also has the corresponding right. Why the same facility of appeal was not laid down in the National Health Insurance Acts is not quite clear, although obviously removal from the panel is not so serious a disability as removal from the Register, to which appeal refers in the case of nurses, dentists, and midwives. The Medical Benefit Consolidated Regulations of 1923 make it clear that the panel practitioner has no right to have a special case stated on questions of law arising out of inquiries under Part VI. Part V. of these Regulations, which contains the provisions relating to disputes, appeals, and so forth, does indeed apply (Art. 35) certain scheduled sections of the Arbitration Act, 1889, to "any appeal made to the Minister under these Regulations against a decision of a Committee," and Section 19 of the Regulations runs: "The Minister may at any stage of the proceedings on an appeal, and shall, if so directed by the Court or Judge, state in the form of a special case for the opinion of the Court any question of law arising in the course of the appeal." But this Section 19 was omitted from the 1920 Regulations and is still omitted in 1923, just as in 1920, with the result that there is no right of appeal for a practitioner whose continuance on the list has been made the subject of an inquiry under Part VI. The omission does not trouble the great majority of practitioners who would prefer to go before a tribunal of three, two of whom are doctors, than to go before any other tribunal, judicial or otherwise. In any case Section 19 of the Arbitration Act contemplates appeal only on questions of law, not on questions of fact, and it is

A complete account of fractional antigens is given in a series of articles by Much and Leschke.[7] These workers divide their antigens into three groups. 1. Tuberkelbazilleneiweiss, named Tb. A. The bacilli were defatted by prolonged extraction with benzoyl chloride. There was no preliminary acid treatment, this being hardly necessary when it is remembered that a fair quantity of hydrochloric acid would be set free during the extraction process. 2. Fettsäuren und lipoide tuberkelbazillen, containing the lipoid and fat content. 3. Tuberculonastin, an alcohol and ether extract of the above. Tested as antigens by the complement-fixation test on various known sera, it was found that where Koch's B.E. gave positive results in 77·1 per cent. tuberculonastin gave only 56·2 per cent. of positives, the fatty-acid antigen 14·3 per cent., whilst the defatted antigen gave only 7·1 per cent. of positives. These three antigens were used by Much and Leschke for therapeutic purposes, although they refrain from stating how the results compare with Koch's antigens. In his book, "Die Immunitätswissenschaft," Much[8] quotes his work with Deycke on defatted and other antigens at great length. It is curious that here again no statement is made as to the relative values of these various antigens as compared with Koch's preparations. Judging from complement fixation, defatted antigen appears inferior to ordinary B.E. Prof. Dreyer is working with an antigen defatted in a very similar manner to the Tb. A. of Much and Deycke, and it is on the clinical and experimental results that interest will centre.

SUPERFICIAL SENSIBILITY.

IT is more than probable that the skin and touch have been associated in the mind of man from the time when he first analysed his feelings. The ancient philosophers dealt with the special senses according to their particular theories, and among these Democritus may be mentioned as upholding the opinion that all the senses were but modifications of that of touch. Aristotle held quite opposite views, and to him the skin was a necessary adjunct to the organ of touch, for certain philosophical reasons, but was not that organ itself, in the sense in which the eye and ear might be termed the special organs of sight and hearing. Galen subsequently made the distinction more definite, in that he seemed to lay more stress on the covering than on the tactile functions of the skin. It was, however, described later by Constantinus as the organ of touch, tactile sensibility varying in different places. After this we find Casserius, in the seventeenth century, going back to the opinion of Democritus concerning the essential unity of the senses, but he referred differentiation between them to the "sensitive faculty" in the brain: among the ancients this faculty lay in the proper organs of the senses, quite apart from the brain. Malpighi now described tactile papillæ in the skin, and referred tactile impressions to these, considering them to be formed by ends of nerves. Molinetti shared with Democritus and Casserius the view that all sensations are modifications of touch-sense, but with him the differentiation had to do with variation in number and arrangement of nerves, an opinion supported by Buffon in more recent times with much ingenuity. Thus there has been a slow progress in clarification of view about touch, a correction of opinion about functions of sense-organs, increasing appreciation of the rôle of the nervous system, search for anatomical bases for opinions, and analysis of the senses themselves. To-day we find the progress still going on, and the analysis becoming more critical. Head, by his researches and by the classical experiment on his own arm, led us some years ago to distinguish between deep and superficial sensibility, and gave reasons for subdividing this last into two classes. Prof. J. S. B. Stopford, who has done much sound and philosophical work in the last few years on wounded nerves, has proposed recently that deep sensibility should also be divided into classes corresponding with those of cutaneous sense. Prof. Stopford has added much to our knowledge of nerve distribution in the upper limb, and has described fibres to the deeper layers from nerves usually considered purely sensory, thus giving a structural basis for certain of his conclusions. He suggests[1] thalamic and cortical terminations for tracts subserving protopathic and epicritic sensation respectively. Evidently anatomico-physiological analysis of touch-sense is progressing satisfactorily, but the end of it is not yet.

THE NEW B.P. CODEX.

A NEW and revised edition of the British Pharmaceutical Codex has just been issued by the Pharmaceutical Press (72, Great Russell-street, London, W.C.), by direction of the Council of the Pharmaceutical Society of Great Britain. This is the third edition since 1907 when the Codex first appeared. The scope of it was then defined as an imperial dispensatory for the use of medical practitioners and pharmacists, containing information respecting all drugs and medicines in common use throughout the British Empire, including the principal substances and preparations which are official in the pharmacopœias of France, Germany, and the United States, as well as those described in the British Pharmacopœia. The original work contained in the volume represents the fruits of arduous labour and extensive investigations, partly performed in the research laboratory of the Pharmaceutical Society, but a large proportion privately undertaken by individual members of that Society. The present edition contains much new matter and has been brought into line with the British Pharmacopœia of 1914 and the ninth revision of the U.S. Pharmacopœia. While the genera plan of the work has been left unaltered, the chemical nomenclature has been brought into line with modern views and the physiological action of important substances has been extended in accordance with the latest development of medical research. Doses are now set out in metric units with a parenthetic alternative in grains and minims. The extent of time-saving to which a general adoption of the metric system would give rise is apparent in a table giving the percentage equivalents of grains (minims) in pint, pound, and ounce. The index is a marvel of completeness and the Codex, 1923, forms a work of reference of great value and accuracy.

FURTHER DISCUSSIONS ON THE DIET OF THE WEANLING.

NOT much more than two years ago the Society of Medical Officers of Welfare Centres, now incorporated as a group of the Society of Medical Officers of Health, discussed at some length the choice of a diet for a child from weaning to the age of 5 years. The meeting was fully reported in our columns and our comments thereon led to some lively correspondence. It appeared that the subject was to be further developed, for among the items in the programme issued of the proposed activities of the *Conference* on Infant Welfare held during Baby Week at 117, Piccadilly, London, W. 1, was a discussion by this group on the Feeding of Children from 5 Years of Age, to be opened by Prof. E. Mellanby. This would appear to us a subject of interest to practitioners as well as to parents and to the elementary schools providing dinners to infant classes, though presumably designed for the information of medical officers of infant welfare centres, giving parting instructions on dismissing the child to parental care. Owing partly to an apparent misprint in the programme and to some extent to the absence of Prof. Mellanby, the debate was less illuminating than might have been expected. It dealt with the feeding of children, not after 5 years old, but from 1 to 5, and it will be seen by our report

Annotations.

"Ne quid nimis."

THE CENTENARY OF THE LANCET.

THE dinner in celebration of the completion of the hundredth year of THE LANCET will be held in London on Wednesday, Nov. 28th, 1923. Sir Donald MacAlister, President of the General Medical Council, will take the chair, supported by the President of the Royal Society, the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the Chief Medical Officer of the Ministry of Health, the President of the Royal Society of Medicine, and the President of the Medical Society of London. Dr. J. H. W. Laing and Mr. H. D. Gillies (7, Portland-place, London, W.) are acting as Honorary Secretaries to the Dinner Committee.

THE INFECTING AGENT OF EXANTHEMATIC TYPHUS.

Prof. W. Barykin and Dr. N. Kritsch, of Moscow, have announced[1] the discovery of what they claim to be "with very great probability" the cause of exanthematic typhus. Prof. Barykin has for four years been investigating typhus. He early found that the typhus process so altered the blood-vessels as to facilitate infection of the blood-stream with myriad micro-organisms, all of whom the blood of typhus cases agglutinated. It was in consequence of these very various infections that complications were so frequent, occurring as they do in 30 or even 60 per cent. of the cases. Secondary infections being so frequent, he concluded the true cause could only be discovered in the body in the early days of the disease, in the pre-eruptive stage, and that he could hope for no help from agglutination reactions. So he investigated 23 cases of pre-eruption typhus, finding nothing then in the blood but some small elements ($0{\cdot}4$–$1{\cdot}5\mu$), closely resembling *Rickettsia prowazeki* ($0{\cdot}64\mu$) or young forms of Plotz's bacillus ($0{\cdot}9$–$1{\cdot}9\mu$); to these he gave the name *Microbion typhi exanthematici*. He and Afanassieff proceeded then to seek for it in 150 cases of human typhus, in 200 typhus-inoculated guinea-pigs, and in specimens from 11 early post-mortem examinations. They found that in the early days of the stage of invasion the bacterium (there seems no occasion for the term microbion) is so constantly present in the blood of the guinea-pig that, by its presence or absence, diagnosis can be definitely made even in the pre-eruptive stage, but the search may last for hours, and many films may have to be examined. It was in the blood that the bacterium was first found, but it occurs in far greater numbers in the cells of the brain, the spleen, and the suprarenals, growing within the cells into clusters, and in time killing the cells. The bacterium is not discoverable during the stage of incubation, and it could not be found in the organs of a hundred uninfected guinea-pigs and men. The investigation next concerned itself with lice; the bacterium was found in the intestinal epithelium and intestinal contents of 1050 of 1500 infected lice; it could not be found in lice from uninfected men. Further, in the intestinal contents of 280 infected lice, the bacterium was found in 192; it was found in the epithelium in 14 of the infected, in only one of the controls. It was difficult to make cultures of the bacterium until Kritsch hit upon the idea of making a medium out of the tissues in which the "microbion" is, customarily, most plentifully found. A pancreatised sterile broth being prepared, small portions of brain or spleen were rapidly removed under aseptic precautions, at early post-mortems of men or guinea-pigs dead in the first stage of the disease; these portions were minced very finely, mixed with the broth, and tubed. The tubes were over-layered with paraffin and incubated at 37° C. During the first ten days, the bacteria which had at first appeared, had gradually died out, and then the "microbion" might appear; it begins to grow in the tissue cells, only later spreading to the fluid. It begins as clusters of Gram-negative cocci, very small; later they increase in size and begin to stain with Gram. It is non-motile. At 37° C. they remain alive for 4–6 weeks, but die in an hour at 50° C.; once established it can be grown on pancreatised spleen- or brain-broth agar, on which it grows, aerobically, in round, glistening colonies. The growth is difficult to emulsify in normal saline; it will not grow in broth. Lastly, of 22 guinea-pigs inoculated with these cultures, 14 became infected; their disease, clinically, closely resembled typhus; few of them died, but in the ten that were killed at the close of the pyrexial stage there were found—hyperæmia of the spleen follicles with hyperplasia, hyperæmia of the suprarenals, hyperæmia and œdema of the brain; in other words, the histo-pathology of the infection produced by the bacterium in the guinea-pig is identical with that originated by typhus in man. On the strength of these observations Prof. Barykin and Dr. Kritsch make the claim that the bacterium is "very probably" the cause of typhus fever. We call attention to their interesting and suggestive observations. In spite of all the work which has been done upon it, the *Rickettsia* is not yet firmly habilitated as the cause of typhus. That the blood in typhus patients is invaded by other organisms needs confirmation. But the Russian authors have found a ready means of cultivating the infecting agent which will pave the way for further investigation.

ACID-FASTNESS.

ALTHOUGH acid-fastness has always been associated with the fatty constituents of the bacillus, this property cannot be removed from the organism by extraction with fat solvents alone. This fact may be considered well established, as Dr. J. A. Shaw-Mackenzie reminds us in his letter in another part of this issue. Aronson[1] it was who showed that if the organisms are treated with an acid in addition to fat solvents the acid-fastness can be completely removed by prolonged extraction. This important piece of work was confirmed by many workers, including Bulloch and Macleod,[2] Much and Deycke,[3] and others. The latter observers also showed that any organic acid such as lactic would answer the purpose. Prof. Dreyer finds that he can remove the acid-fastness by the action of formalin and fat solvent extraction. No explanation is advanced for the action of formalin in place of the usual acid treatment, but it seems probable that it may act by virtue of the appreciable amount of formic acid always present in 40 per cent. formalin. If this is the case the action would be analogous to the reaction of Much and Deycke with lactic acid. The bacilli obtained by this combined formalin and fat extraction treatment are made into an antigen apparently possessing valuable therapeutic properties. Since the discovery and preparation of tuberculin by Koch a large amount of literature has collected on the methods of preparation of tubercular antigens. By varying the technique each worker has hoped to produce an antigen more sensitive for both diagnostic and therapeutic purposes. Gabrilowitsch[4] was probably the first to work on fractional antigens. In 1891 he described a "*tuberculum purum*," obtained by extracting bacilli with xylol, ether, chloroform, and alcohol. This preparation was used for therapeutic purposes. Armand-Delille,[5] in 1902, worked with ether- and chloroform-extracted bacilli, whilst Leber and Steinharter,[6] in 1908, used an antigen prepared from chloroform-extracted bacilli on 350 patients.

general malaise, and great pain, most marked in the affected joints. Locally there is a small circumscribed swelling and slight tenderness, but no cases of abscess formation or of necrosis have been observed, nor has there been any disturbance of the function of the renal, vascular, or hæmopoietic systems. The reaction subsides completely in 24 or at most 48 hours and the patient feels perfectly well. Combined with the sulphur therapy, such external applications as hot air, baths, massage, and passive movements should be persisted in, and it is important that these should not be omitted, for it is only during the sulphur treatment that their maximum benefit can be obtained. The result of the treatment on the joints is that there is rapid diminution of pain, the swelling decreases, and the range of movement is markedly increased, while the general condition of the patient correspondingly improves. Acute affections which respond to salicylates were not treated by this method.

COMMITTEE ON THE USE OF PRESERVATIVES IN FOOD.

As we recently announced, a deputation of medical officers of health and others to the Ministry of Health, urging the need for further control in the use of food preservatives, received the gratifying assurance that a committee was being appointed to consider the whole question. The personnel of this Committee is as follows: Sir H. C. Monro, K.C.B. (chairman); Prof. W. E. Dixon, M.D., F.R.S.; Sir A. D. Hall, K.C.B., F.R.S.; Dr. J. M. Hamill; Mr. O. Hehner, F.I.C.; Prof. F. G. Hopkins, F.R.S.; Dr. G. R. Leighton; Dr. A. P. Luff; Dr. C. Porter; Mr. G. Stubbs, F.I.C. They are asked to inquire into the use of preservatives and colouring matters in food and to report:—

1. Whether the use of such materials or any of them for the preservation and colouring of food is injurious to health, and, if so, in what quantities does their use become injurious.

2. Whether it should be required that the presence of such materials and the quantities present in food offered or exposed for sale should be declared.

The secretary of the Committee is Mr. A. M. Legge, of the Ministry of Health, Whitehall, S.W., to whom all communications should be addressed.

LEGITIMATE REQUIREMENT OF OPIUM.

IN the July number of the *Contemporary Review* appears an article by Sir William Collins dealing with the present position of the opium traffic. It will be remembered that Sir William Collins, together with Mr. (now Sir) William Max-Muller, signed, on behalf of the British Government, the Convention drafted at the First International Opium Conference held at The Hague in 1912. Since 1919 the League of Nations has been entrusted with the carrying into effect of the Convention, in so far as the States which are members of the League are concerned. We have repeatedly referred to the work of the Advisory Committee on Opium, appointed by the Council of the League to supervise the execution of the Convention.[1] The Committee has continued the work formerly carried out by the Netherlands Government in endeavouring to secure ratification of the Convention by all the Powers, and has made an attempt, in coöperation with the Health Committee of the League, to ascertain the amount of opium, morphia, cocaine, and heroin required for legitimate consumption, but so far with inconclusive results. The problem of the "legitimate" needs of one country and another has given rise to much discussion, particularly with regard to India. The Indian Government takes its stand on the findings of the Royal Commission of 1895, to the effect that prohibition of poppy cultivation and the manufacture and sale of opium in British India would involve the destruction of the heavy export trade in Bengal opium to China and elsewhere, and would inflict a heavy loss of public revenue on the Government and people of India. The Commission also found that opium was a "universal household remedy," that it was "extensively administered to infants," and that it was used as a stimulant and prophylactic against malaria and fever. The Indo-Chinese trade, however, was terminated in 1917; some 14,000 chests of Indian Government opium are annually exported to meet the "legitimate requirements of the non-China markets"—the latter including the Straits Settlements and North Borneo. The Indian Government condemns opium-smoking as "essentially a social vice," and, speaking generally, it is their policy to "confine the use of the drug within the narrowest possible limits." The manufacture of opium for smoking in India is said to be prohibited except by the individual for his own use. With regard to China, it is to be regretted that this country, which was reported to be free from poppy cultivation in 1917, has since resumed a large production of opium, by the action of provincial governors in defiance of commands from Peking. In a recent issue we dealt with the estimated legitimate needs of China—2000 oz. for a population of 400 millions with a yearly sickness incidence set at 20 millions.[2] At the session of the Advisory Committee held at Geneva in June, the United States representatives pressed for limitation of production of the drugs dealt with in the Convention to the amounts required for strictly medicinal and scientific purposes. This proposition was apparently approved subject to a reservation on behalf of the Government of India, and to a declaration that so long as opium-smoking is not, as the Convention of 1912 contemplated it should be, suppressed, opium raised for that purpose is to be deemed legitimate. Sir William Collins in his article described a personal inquiry into the legitimate use of the drugs in question, as follows:—

> "With the assistance of Mr. Langford Moore, pharmacist to St. Bartholomew's Hospital, I have recently ascertained *that at ten* of the larger London hospitals, treating 70,000 in-patients and 550,000 out-patients a year, the amount of opium used is about 40 lb. per annum, of morphia 5¼ lb., and of cocaine just over 9 lb. These relatively modest amounts, which suffice for the legitimate medical treatment of 620,000 sick and injured persons in a year, contrast strikingly with the hundreds of thousands of kilograms of opium annually raised, and the tons of morphia and cocaine annually manufactured and exported."

These findings form another useful indication of the actual quantity of drugs of addiction which is necessary for the use of the world; it is for the League of Nations, with the aid of the United States, to strive for prevention of any output in excess of that quantity.

SIMULTANEOUS OBSERVATIONS ON GASTRIC AND DUODENAL SECRETIONS.

THE interesting studies on human digestive secretions which have emanated from the Department of Physiology of the University of Edinburgh have been extended by the introduction of a new technique. We recently published[3] an article by Dr. A. R. Matheson and Dr. S. E. Ammon describing the vigorous secretion of gastric juice which appears in the fasting human stomach in response to a hypodermic injection of histamine. In the current number of the *Edinburgh Medical Journal* Drs. R. K. S. Lim, A. R. Matheson, and W. Schlapp give a preliminary account[4] of their latest work. They introduce two tubes, the first into the duodenum, the second into the stomach, and by applying continuous aspiration to both of these they are able to recover the main bulk of the secretions both of the stomach and the duodenum; the method has the great additional advantage that the duodenal secretion is unadulterated with gastric contents, these being removed separately. Three experiments on normal subjects are described: in all of these a marked increase in gastric secretion was

[4] Edin. Med. Jour., July, 1923.

(see p. 69) that the principal speakers and the points raised did not greatly differ from those at the 1921 discussion. Dr. Eric Pritchard opened with an exposition of his well-known views, which are too sane and broad to stimulate active opposition. Dr. Harold Waller has not found reason to modify his attitude of scepticism on milk as the ideal diet for the healthy weanling. The discussion yielded questions rather than information; Dr. Pritchard resisted firmly attempts made to force him to make oracular pronouncements, intimating that neither he nor anyone else is yet in a position to dogmatise on the ideal diet for children—or indeed for adults. The difficulty is not one of simple progression towards a known goal, but concerns rather the solution of the problem of finding without mathematical instruments the centre of a scalene triangle whose dreaded angles are malnutrition, constipation, and dental caries. It may be easy to find a point equidistant from any two of these acknowledged evils, only to find ourselves perilously near the third. Diets with little indigestible matter are not likely to give stimulation to the bowels of children of costive habit, and bulky carbohydrate foods, though condemned by the dentist and by the dietician, are often prescribed by the physician. Again, the hard food requiring mastication which is desirable to keep even milk teeth in good condition and promote the cleansing flow of saliva may well be beyond the digestive powers of the gastric juice of a very young child, whereas lump or barley sugar, cheap, digestible, of excellent energy value, soluble, and consumed with avidity by children, is hardly ever prescribed even for the marasmic child, possibly out of undue consideration for the teeth. A compromise must be arrived at, and no progress will be made until it is recognised that the contradictory advice so bewildering to mothers is the result of a real conflict between the aims of individual specialists who consider as of primary importance the general nutrition, the conservation of the teeth, or the maintenance of regular defæcation without aperients.

AN INDICTMENT OF PROTEIN TREATMENT.

THE idea that stimulation and irritation of the tissues can be exploited for the benefit of the patient is far from new, and Virchow's teachings in this connexion date many decades back. But it is only of late that protein activation in one or other of its aliases has become a popular vogue, and in Germany, at any rate, the practice of giving remedies by parenteral injection for almost every complaint has become very common. If this treatment is as effective as the list of substances for parenteral injection is long, there would surely be no scope for any other form of treatment. The favourites in this list would seem to be sterilised milk or a 5 per cent. solution of casein, a suspension of sulphur in olive oil, collargol, phylacogen, jodormone (a compound of iodine with horse serum), sanarthrit (a cartilaginous extract), yatren-casein, vaccineurin, ophthalmosan, and other milk products. There are many other proprietary remedies in the same class, and most, or all of them, are supposed to be beneficial on account of focal and general reactions. A feature of this form of medication, which is very impressive from the patient's point of view, is the fact that the physician's prophecy that a febrile reaction will occur in so many hours actually comes true. There is nothing which impresses the patient and gives him faith in both physician and remedy so much as a prognosis which comes true not merely to the day, but to the hour; to have a reputation for omniscience is helpful in practice, but to be blest with a reputation for prescience may be even better. During the last year or two doubts have been expressed in more than one quarter as to the permanency of the effects of "Reizterapi" (as it is known in the Scandinavian countries), and at the Bispebjaerg Hospital in Copenhagen a systematic attempt has been made by Dr. H. Jansen and Dr. E. Begtrup[1] to study the effects of this treatment on chronic disease of the joints. To make the trial as fair as possible, they dispensed with other remedies in as many cases as possible, and selected comparatively early cases of joint disease for their tests. These were made with subcutaneous, intramuscular, or intravenous injections of caseosan, intragluteal injections of a suspension of sulphur in olive oil or of plain, sterilised cow's milk. Intravenous injections of collargol and subcutaneous injections of phylacogen were also given, and two new preparations not yet put on the market by their German inventors, were also tested. The records of many of the cases are published in detail, and common to practically every case was the observation that whether the immediate results were good, bad, or indifferent the patients were ultimately little or no better off than before. Sooner or later practically all these patients had to fall back on hydropathic and other physical remedies, the effects of which were on the whole very much better than those of "Reizterapi." The authors' fair tests and critical analysis of this treatment may chill the ardour of some of its supporters.

THE CHILDREN'S SANATORIUM AT HOLT.

THE Children's Sanatorium at Holt, Norfolk, was originally intended only for early cases of pulmonary tuberculosis in the poor. Poverty, however, is a relative matter, and the governing body has recently decided to set aside a ward for children of middle-class parents who are not in a position to afford the necessarily high fees of private sanatoriums. The weekly charge for these patients will be £2 2s., and they will have the same treatment as the other children except for the sleeping arrangements. It is satisfactory to learn from the last annual report of the sanatorium that the average duration of treatment is as long as 41 weeks, and that it makes no "cure-you-while-you-wait" claims. During 1922 all the available 48 beds were occupied, and the number of in-patients was 56. We are sure that the new arrangement will materially increase the usefulness of this institution.

SULPHUR IN THE TREATMENT OF ARTHRITIS.

SULPHUR has long been used in the treatment of skin affections and as an adjunct in the treatment of syphilis, but only recently has it been used at all extensively for the relief of joint affections. The chronic rheumatoid and osteo-arthritic conditions might well be placed foremost among the diseases which cause the greatest and most prolonged suffering and disability to the patient and the greatest perplexity to the practitioner, the very hopelessness of all known methods of treatment driving him to despair and leading him to expend his energy and thought on other more profitable fields of research. From the reports received it appears that sulphur given intramuscularly in the form of an oily emulsion has a specific effect on chronic arthritic conditions, and while not in every case producing complete restoration of function, affords a very great measure of relief from pain and increase in mobility, thus enabling the patient to return to a useful and comfortable existence. Dr. Herbert Hayn,[1] of Breslau, reports 11 cases of different forms of arthritis, including acute and chronic rheumatoid and osteo-arthritis, gonococcal arthritis, and gout, some of many years' duration and completely bedridden. In all an undoubted improvement was seen, most noticeable in those cases which had resisted the orthodox methods of treatment, and bedridden patients left the hospital walking. The sulphur therapy consists of intramuscular injections of a 1–8 per cent. emulsion of sulphur in oil, repeated at intervals of 5–6 days. The number of injections required varies, in the cases reported from 5–13. The immediate reaction to the injection, which is independent of the quantity given, is severe. The temperature rises within 12 hours to 40° C. and a rigor occurs, the patient complains of intense headache, circular suture of any tube tends to narrow its lumen, and the urethra is neither so large nor so distensible that this narrowing can be permitted with impunity. The passage of large bougies frequently tears the freshly united tissues, inflicting further injury which can only repair by the formation of more scar-tissue; there results a vicious circle.

---

[1] Ugeskrift for Laeger, June 14th, 1923.

[1] Deutsche medizinische Wochenschrift, May 25th, 1923.

The Principles of Treatment and Their Application.

Certain principles may be outlined: (1) Urine must not be allowed in contact with the damaged area until healing is complete. (2) The torn ends of the urethra must be brought into apposition. (3) No foreign body, such as a catheter, must be allowed in contact with the urethral wound during the process of healing. (4) After union, the urethral channel at the site of the injury must not be re-injured by the frequent passage of unnecessarily large bougies. On these principles all cases of rupture of the urethra in which blood escapes from the meatus require operation. In contusions without bleeding from the urethra the use of the catheter is permissible and may suffice, but if there is increasing difficulty or a swelling develops in the perineum, operation is indicated. There is a type of case in which the symptoms, after an injury to the perineum, are often accounted too slight to need treatment; there are pain and passage of a little blood, but there is little or no difficulty in micturition. In these very slight cases operation, even if limited to perineal drainage behind the site of the injury, will have happier results than expectant treatment.

Treatment must be carried out before attempts to micturate have driven urine into the tissues around the canal or involuntary escape from an over-distended bladder has led to the same result. A delay of several hours may be unavoidable before the patient can be removed to a properly equipped hospital or the services of an operating surgeon secured, and certain temporising measures may have to be employed. The patient must be instructed not to attempt to micturate; a sedative may be administered to help him to desist. If operation cannot be undertaken within two or three hours of the accident, the bladder is distended and desire to micturate insistent, the bladder should be punctured suprapubically, using local anæsthesia, or without if a fine trocar and cannula, with aspiration apparatus, be used. The trocar is removed lest a fistula should develop, and the puncture repeated if necessary.

Operative treatment involves perineal section, exposure and repair of the injury, and temporary perineal drainage of the bladder. The patient is in the lithotomy posture in a good light and a catheter or a rigid staff is passed to the site of the injury. An incision of ample length is then made, from the base of the scrotum to near the anus, and is deepened until the urethra is reached. The site of the tear, indicated by blood-clots, should be fully exposed and all clots wiped away or removed gently with a spoon until the exact amount of damage is ascertained. When the urethra is completely divided it may be a little troublesome to find the retracted proximal end; urine escaping or expelled by suprapubic pressure may furnish a useful guide. I have never met a case in which it was necessary to open the bladder for retrograde catheterisation. The distal end, if not at once found, can be identified by passing a rubber catheter from the meatus. The ends once found, can nearly always be approximated and should be fixed together by sutures joining only the roof and the sides of the canal. The floor is then represented by a diamond-shaped space which, when it heals by the approximation of the surrounding tissues, leaves the urethral channel larger at the site of the injury than elsewhere, thus allowing for some contraction which will inevitably occur. A rubber catheter may, if desired, be passed from the distal to the proximal urethra during the process of suturing, but in any event must be removed when the latter is completed. When the tear is limited to part of the circumference it is diminished by sutures but the floor is always left open. The approximation of the urethra being complete, the floor of the proximal end is incised in its long axis for half an inch backwards from the site of the tear. A rubber catheter, size 12 or larger, is then passed from the perineal wound through the incision in the floor of the posterior urethra into the bladder, and is fixed to the skin margin with a silk-worm suture. The catheter now lies in the posterior part of the perineal wound, while the sides and edges of the anterior part are drawn together over the sutured urethra. Only one or two stitches are necessary as the parts lie naturally in contact when the legs are extended side by side. If the urethra is pulped so that the gap cannot be bridged a catheter may be passed from the distal into the proximal segment; the segments are then drawn together as nearly as possible, the deficiency being made good by the surrounding tissues aided by any shreds of urethral mucous membrane, which are carefully cherished and laid along the catheter. It may be necessary to reconstruct the urethra with flaps of fascia lata or by some other device, but it is wonderful how often the channel is usefully restored without these aids when the urine is conducted away from the area during the process of healing. Some surgeons prefer to perform suprapubic cystotomy, but this is no more efficient than the perineal drain. While the catheter remains in the bladder it must be washed out twice daily to ensure that its lumen is kept free. As phosphates are liable to form around its end the patient must take 1 drachm of acid phosphate of soda and 15 gr. of urotropin in a glass of barley-water each day. The drainage catheter is removed in ten days, after which urine will escape from the perineum for a week or so and later will find its way through the normal channel. Three weeks after the operation, a Lister bougie 9/12 or a silver catheter No. 10 is very gently passed into the bladder; this will present no difficulty if the roof of the urethra is carefully followed. No force is permissible and no larger instrument is necessary. Three weeks later the same instrument is again used and if it passes easily need not be tried again for two months. If narrowed the passage should be dilated until it admits the 9/12 Lister, but no further. A similar instrument should be passed quarterly for a year, afterwards at increasing intervals.

Complications.—Old and Neglected Cases.

Secondary hæmorrhage on removal of the catheter from the perineum is treated by its reintroduction for 24 hours or by packing with iodoform gauze soaked in 1 in 1000 adrenalin solution. A tiny fistula persisting in the middle of the perineal wound may be cured by applications of pure carbolic or nitrate of silver fused on a straightened hairpin or a touch with a fine cautery point. In those cases in which extravasation has already occurred, the perineal swelling must be freely incised down to the site of injury and further incisions made wherever necessary. When possible the proximal urethra must be found and a catheter passed along it into the bladder as already directed, but no prolonged attempt should be made to expose the ends by dissection amidst tissues already infiltrated with sepsis. The main indication is to provide a ready escape for urine and products of infection. If this is successful the urethra may heal or a secondary operation may be carried out when the swelling has subsided.

Rupture of the Urethra Complicating Pelvic Injury.—In this condition the urethra is nearly always torn just at the apex of the prostate and extravasation occurs into the pelvic cellular tissue. The accident is an absolute indication for surgical interference and it is extremely important that it should be carried out before extravasation has occurred. Procedures already detailed may have to be supplemented by suprapubic drainage of the bladder as well as by incisions above the iliac crests for the relief of extravasation. Healing may occur with some deviation of the channel which may render it difficult to pass solid instruments into the bladder, though there may be no stricture or interference with micturition.

G. Grey Turner, M.S., F.R.C.S. Eng.,
Surgeon, Royal Infirmary, Newcastle-upon-Tyne.

obtained after administration of histamine, the increase being both in volume and in concentration of acid with a resultant great augmentation in total acid secretion. In two of the subjects there was no increase in duodenal secretion, and the slight increase in the third is believed to have been due to some escape of gastric contents into the duodenum. One of the most important lessons of this work would seem to be its reiteration of the fact that patience and care on the part of the observer are the only requisites for performing extensive experiments on the alimentary canal in the human subject. Duodenal tubage for diagnostic and therapeutic purposes is an everyday procedure in several clinics both in the United States and in Austria; our Edinburgh colleagues have again demonstrated that simultaneous passage of two tubes is a relatively easy matter and that useful observations can thus be obtained.

CEREBRAL CYSTS.

According to Dr. H. G. Jacobi,[1] of the Lenox Hill Hospital, New York, who records a case of his own, cerebral cysts are of infrequent occurrence and their detection by clinical means is extremely difficult. In most cases the diagnosis is not established until the autopsy. Of 299 cases of brain tumour in children collected by Starr, 30, or nearly 10 per cent., were cysts, which occupied the following situations: basal ganglia and lateral ventricle, 1; pons, 1; medulla, 1; base, 1; cerebellum, 9; and centrum ovale, 15; 2 of the tumours were multiple. The formation of cysts has been attributed to a variety of causes, perhaps the best classification being that of Bruns, who divided cysts into five groups according as they were: (1) of congenital origin; (2) parasitic, due to the cysticercus or more rarely the echinococcus; (3) traumatic, developing around spicules of bone; (4) the result of brain softening; (5) without any accountable ætiology. Dr. Jacobi's case, which was in an infant, aged 1 year, presented the following features of interest: (1) A sudden onset, simulating an acute infectious process; (2) indefinite signs and symptoms, making an ante-mortem diagnosis impossible; and (3) the presence of hyperglycæmia and glycosuria possibly due to pressure of the cyst on the fourth ventricle, as in the well-known experiment of Claude Bernard. Death took place in coma after three weeks' illness, and the autopsy showed a cyst containing creamy yellowish fluid situated beneath the posterior horn of the right lateral ventricle. From the chemical analysis of its contents, which showed that the principal constituent was pseudomucin, Dr. Jacobi is inclined to regard the cyst in his case as being of the proliferative type and of congenital origin.

THE INTERNATIONAL CONGRESS OF SURGEONS IN LONDON.

On Tuesday next the Sixth Congress of the International Society of Surgery opens at the House of the Royal Society of Medicine in London. The programme, which is an attractive one, is set out on p. 99. The Congress brings to this country a number of surgeons of world-wide distinction. The veteran Dr. W. W. Keen, of Philadelphia, now in his eighty-seventh year, expects to be present. Among the members of the committee who will take part are Prof. F. de Quervain, of Berne; Prof. Henri Hartmann, of Paris; Prof. Johan Nicolaysen, of Christiania; Dr. Th. Jonnesco, of Bucharest; Prof. C. F. A. Koch, of Groningen, and Prof. C. Willems, of Liége, the President of the Committee. Dr. William Mayo, of Rochester (Minn.), and Dr. Banting, of Toronto, will take part in the discussion on endocrine surgery; Dr. Crile, of Cleveland, in that on operative shock. The foreign guests will receive a warm welcome, not only officially from the Foreign Minister and the Minister of Health, but also from their surgical friends and colleagues in this country.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXVIII.—THE TREATMENT OF TRAUMATIC RUPTURE OF THE URETHRA.

Traumatic rupture of the urethra is a comparatively rare accident not in itself especially dangerous; but if mismanaged serious complications may ensue and the troublesome stricture which commonly follows has given it an unenviable notoriety.

Pathology.—The accident occurs (*a*) without injury to the bony pelvis; (*b*) as a complication of injury to the latter. In the former case the injury involves the urethra just in front of the triangular ligament in the region of the bulb, while in the latter it is above the ligament and therefore intrapelvic. In either case the urethra may be contused without laceration, or its mucous membrane may be partially torn or completely severed. In contusion there may be some submucous tearing of the urethral wall—interstitial rupture—but the mucous membrane is intact. In partial rupture a gaping wound involves the whole thickness of some part of the wall. In complete rupture there is usually a complete transverse tear, when the ends retract to the extent of an inch or more and they also contract; the tendency to occlusion is further aided by the pursing up of the torn mucous membrane and the accumulation of blood clot between the ends. The laceration may, however, be oblique or irregular, or a section of the whole urethra may be pulped, so that it subsequently necroses or is converted into a mass of scar-tissue. The extent of the injury disclosed when the parts are exposed is generally much greater than would be anticipated from the symptoms and physical signs. The outstanding features of urethral injuries are: (1) effusion of blood; (2) extravasation of urine, local or widespread; (3) infection. Some of the bleeding occurs into the lumen of the canal, escaping through the meatus, but a considerable amount infiltrates the tissues outside the urethra and between the margins of the wound in its walls. The extravasation of urine may be localised to the immediate vicinity of the injury, or may be more widely diffused into the cellular tissue of the perineum delimited by the fascia of Colles, or into the corresponding tissue outside the peritoneum where the injury is above the triangular ligament. Infection may be limited to the parts surrounding the urethra, with or without a localised abscess, or may follow the extravasation.

How Healing is Brought About.—When the urethral wound is kept in apposition, and there is no infection, healing readily takes place with a minimum of scar-tissue; otherwise, healing can only occur slowly by granulation with the maximum of scar-tissue. In complete rupture the channel may be fortuitously restored though seriously narrowed, but more commonly complete obliteration of a section of the urethra occurs, the urine escaping through sinuses.

Faults in Current Teaching.—Many text-books teach that an attempt should be made to pass a catheter into the bladder, the instrument being tied in and left for eight to ten days. Should catheterisation be impossible, perineal section is advocated, the urethra to be carefully and completely sutured around an instrument. In either case large bougies are to be frequently passed for a few weeks.

Now even if a catheter can be passed, the conditions are not ideal for healing. When a catheter rests in the sphincter, the latter relaxes, allowing urine to trickle by its side into the urethra towards the wound, and this invariably leads to infection. Apart from this leakage, the constant presence of the catheter itself acts as an irritant and is almost always associated with some slight infection—harmless in the normal urethra, but a forerunner of scar-tissue in a urethral wound. Again, it must be recognised that complete circular suture of any tube tends to narrow its lumen, and the urethra is neither so large nor so distensible that this narrowing can be permitted with impunity. The passage of large bougies frequently tears the freshly united tissues, inflicting further injury which can only repair by the formation of more scar-tissue; there results a vicious circle.

---

[1] American Journal of Diseases of Children, June, 1923.

The Principles of Treatment and Their Application.

Certain principles may be outlined: (1) Urine must not be allowed in contact with the damaged area until healing is complete. (2) The torn ends of the urethra must be brought into apposition. (3) No foreign body, such as a catheter, must be allowed in contact with the urethral wound during the process of healing. (4) After union, the urethral channel at the site of the injury must not be re-injured by the frequent passage of unnecessarily large bougies. On these principles all cases of rupture of the urethra in which blood escapes from the meatus require operation. In contusions without bleeding from the urethra the use of the catheter is permissible and may suffice, but if there is increasing difficulty or a swelling develops in the perineum, operation is indicated. There is a type of case in which the symptoms, after an injury to the perineum, are often accounted too slight to need treatment; there are pain and passage of a little blood, but there is little or no difficulty in micturition. In these very slight cases operation, even if limited to perineal drainage behind the site of the injury, will have happier results than expectant treatment.

Treatment must be carried out before attempts to micturate have driven urine into the tissues around the canal or involuntary escape from an over-distended bladder has led to the same result. A delay of several hours may be unavoidable before the patient can be removed to a properly equipped hospital or the services of an operating surgeon secured, and certain temporising measures may have to be employed. The patient must be instructed not to attempt to micturate; a sedative may be administered to help him to desist. If operation cannot be undertaken within two or three hours of the accident, the bladder is distended and desire to micturate insistent, the bladder should be punctured suprapubically, using local anæsthesia, or without if a fine trocar and cannula, with aspiration apparatus, be used. The trocar is removed lest a fistula should develop, and the puncture repeated if necessary.

Operative treatment involves perineal section, exposure and repair of the injury, and temporary perineal drainage of the bladder. The patient is in the lithotomy posture in a good light and a catheter or a rigid staff is passed to the site of the injury. An incision of ample length is then made, from the base of the scrotum to near the anus, and is deepened until the urethra is reached. The site of the tear, indicated by blood-clots, should be fully exposed and all clots wiped away or removed gently with a spoon until the exact amount of damage is ascertained. When the urethra is completely divided it may be a little troublesome to find the retracted proximal end; urine escaping or expelled by suprapubic pressure may furnish a useful guide. I have never met a case in which it was necessary to open the bladder for *retrograde* catheterisation. The distal end, if not at once found, can be identified by passing a rubber catheter from the meatus. The ends once found, can nearly always be approximated and should be fixed together by sutures joining only the roof and the sides of the canal. The floor is then represented by a diamond-shaped space which, when it heals by the approximation of the surrounding tissues, leaves the urethral channel larger at the site of the injury than elsewhere, thus allowing for some contraction which will inevitably occur. A rubber catheter may, if desired, be passed from the distal to the proximal urethra during the process of suturing, but in any event must be removed when the latter is completed. When the tear is limited to part of the circumference it is diminished by sutures but the floor is always left open. The approximation of the urethra being complete, the floor of the proximal end is incised in its long axis for half an inch backwards from the site of the tear. A rubber catheter, size 12 or larger, is then passed from the perineal wound through the incision in the floor of the posterior urethra into the bladder, and is fixed to the skin margin with a silk-worm suture. The catheter now lies in the posterior part of the perineal wound, while the sides and edges of the anterior part are drawn together over the sutured urethra. Only one or two stitches are necessary as the parts lie naturally in contact when the legs are extended side by side. If the urethra is pulped so that the gap cannot be bridged a catheter may be passed from the distal into the proximal segment; the segments are then drawn together as nearly as possible, the deficiency being made good by the surrounding tissues aided by any shreds of urethral mucous membrane, which are carefully cherished and laid along the catheter. It may be necessary to reconstruct the urethra with flaps of fascia lata or by some other device, but it is wonderful how often the channel is usefully restored without these aids when the urine is conducted away from the area during the process of healing. Some surgeons prefer to perform suprapubic cystotomy, but this is no more efficient than the perineal drain. While the catheter remains in the bladder it must be washed out twice daily to ensure that its lumen is kept free. As phosphates are liable to form around its end the patient must take 1 drachm of acid phosphate of soda and 15 gr. of urotropin in a glass of barley-water each day. The drainage catheter is removed in ten days, after which urine will escape from the perineum for a week or so and later will find its way through the normal channel. Three weeks after the operation, a Lister bougie 9/12 or a silver catheter No. 10 is very gently passed into the bladder; this will present no difficulty if the roof of the urethra is carefully followed. No force is permissible and no larger instrument is necessary. Three weeks later the same instrument is again used and if it passes easily need not be tried again for two months. If narrowed the passage should be dilated until it admits the 9/12 Lister, but no further. A similar instrument should be passed quarterly for a year, afterwards at increasing intervals.

Complications.—Old and Neglected Cases.

Secondary hæmorrhage on removal of the catheter from the perineum is treated by its reintroduction for 24 hours or by packing with iodoform gauze soaked in 1 in 1000 adrenalin solution. A tiny fistula persisting in the middle of the perineal wound may be cured by applications of pure carbolic or nitrate of silver fused on a straightened hairpin or a touch with a fine cautery point. In those cases in which extravasation has already occurred, the perineal swelling must be freely incised down to the site of injury and further incisions made wherever necessary. When possible the proximal urethra must be found and a catheter passed along it into the bladder as already directed, but no prolonged attempt should be made to expose the ends by dissection amidst tissues already infiltrated with sepsis. The main indication is to provide a ready escape for urine and products of infection. If this is successful the urethra may heal or a secondary operation may be carried out when the swelling has subsided.

Rupture of the Urethra Complicating Pelvic Injury.—In this condition the urethra is nearly always torn just at the apex of the prostate and extravasation occurs into the pelvic cellular tissue. The accident is an absolute indication for surgical interference and it is extremely important that it should be carried out before extravasation has occurred. Procedures already detailed may have to be supplemented by suprapubic drainage of the bladder as well as by incisions above the iliac crests for the relief of extravasation. Healing may occur with some deviation of the channel which may render it difficult to pass solid instruments into the bladder, though there may be no stricture or interference with micturition.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXVIII.—THE TREATMENT OF TRAUMATIC RUPTURE OF THE URETHRA.

Traumatic rupture of the urethra is a comparatively rare accident not in itself especially dangerous; but if mismanaged serious complications may ensue and the troublesome stricture which commonly follows has given it an unenviable notoriety.

Pathology.—The accident occurs (*a*) without injury to the bony pelvis; (*b*) as a complication of injury to the latter. In the former case the injury involves the urethra just in front of the triangular ligament in the region of the bulb, while in the latter it is above the ligament and therefore intrapelvic. In either case the urethra may be contused without laceration, or its mucous membrane may be partially torn or completely severed. In contusion there may be some submucous tearing of the urethral wall—interstitial rupture—but the mucous membrane is intact. In partial rupture a gaping wound involves the whole thickness of some part of the wall. In complete rupture there is usually a complete transverse tear, when the ends retract to the extent of an inch or more and they also contract; the tendency to occlusion is further aided by the pursing up of the torn mucous membrane and the accumulation of blood clot between the ends. The laceration may, however, be oblique or irregular, or a section of the whole urethra may be pulped, so that it subsequently necroses or is converted into a mass of scar-tissue. The extent of the injury disclosed when the parts are exposed is generally much greater than would be anticipated from the symptoms and physical signs. The outstanding features of urethral injuries are: (1) effusion of blood; (2) extravasation of urine, local or widespread; (3) infection. Some of the bleeding occurs into the lumen of the canal, escaping through the meatus, but a considerable amount infiltrates the tissues outside the urethra and between the margins of the wound in its walls. The extravasation of urine may be localised to the immediate vicinity of the injury, or may be more widely diffused into the cellular tissue of the perineum delimited by the fascia of Colles, or into the corresponding tissue outside the peritoneum where the injury is above the triangular ligament. Infection may be limited to the parts surrounding the urethra, with or without a localised abscess, or may follow the extravasation.

How Healing is Brought About.—When the urethral wound is kept in apposition, and there is no infection, healing readily takes place with a minimum of scar-tissue; otherwise, healing can only occur slowly by granulation with the maximum of scar-tissue. In complete rupture the channel may be fortuitously restored though seriously narrowed, but more commonly complete obliteration of a section of the urethra occurs, the urine escaping through sinuses.

Faults in Current Teaching.—Many text-books teach that an attempt should be made to pass a catheter into the bladder, the instrument being tied in and left for eight to ten days. Should catheterisation be impossible, perineal section is advocated, the urethra to be carefully and completely sutured around an instrument. In either case large bougies are to be frequently passed for a few weeks.

Now even if a catheter can be passed, the conditions are not ideal for healing. When a catheter rests in the sphincter, the latter relaxes, allowing urine to trickle by its side into the urethra towards the wound, and this invariably leads to infection. Apart from this leakage, the constant presence of the catheter itself acts as an irritant and is almost always associated with some slight infection—harmless in the normal urethra, but a forerunner of scar-tissue in a urethral wound. Again, it must be recognised that complete ing to Kenya, it may be said that while limited portions of the high tablelands would appear to be blessed with climatic conditions which should suffice for purposes of stimulation, it is, to say the least, doubtful if this can be predicated of the whole elevated area over which white settlers are scattered, and more especially of Nairobi and its immediate neighbourhood. Still, only time can show, and it should be remembered that we do not yet know if marked changes in the 24 hours as, say, between the day and night temperature or even considerable diurnal variations, can make up for the differences of season as experienced in temperate lands. The future is, as it were, upon the knees of the gods and, as we shall see, there may yet be developments which will modify the climate or enable men to defy it.

---

[1] American Journal of Diseases of Children, June, 1923.

CLIMATE AND HUMAN METABOLISM.

Having considered the broader aspects of this question of the influence of tropical climate upon the white races of mankind it is time to discuss its effect on human metabolism in more detail. Huntington likens the influence of climate upon men to that of a driver upon his horse, and the simile is both homely and apt. He says :—

> "Some drivers let their horses go as they please. Now and then a horse may run away, but the average pace is slow. Such drivers are like an unstimulating climate. Others whip their horses and urge them to the limit all the time. They make rapid progress for a while, but in the end they exhaust their animals. They resemble climates which are always stimulating. In such climates nervous exhaustion is likely to prevail and insanity becomes common. A third type of drivers first whip their horses to a great speed for a mile or two, and then let them walk slowly for another mile or two. They often think that they are accomplishing great things, and they are better off than the two types already mentioned, but they still have much to learn. They are like a climate which has a strong contrast of seasons, one being favourable and the other unfavourable. Still a fourth kind of driver may whip his horse sometimes and sometimes let him walk, but what he does chiefly is to urge the animal gently with his voice, then check him a little with the rein. By alternate urging and checking he conserves the animal's strength, and in the long run can cover more distance and do it more rapidly than any of the others. Such a driver resembles a climate which has enough contrast of seasons to be stimulating but not to create nervous tension, and which also possesses frequent storms whose function is to furnish the slight urging and checking which are so valuable in the total effect, although each individual impulse is almost unnoticeable."

Now, save as regards the fourth type, which cannot be said to exist in the tropics, it is possible to cite countries within the torrid zone furnishing examples of these varieties of climate. The first, the unstimulating, is that met with along tropical littorals, as, for example, the West Coast of Africa, in great forests like those of the Amazon, or in islands like most of the West Indies or the Polynesian archipelago. The second type, producing over-stimulation, can be found only at high altitudes such as exist in the Andes. Parts of Peru—as, for instance, the region of Cuzco—may be cited. The third type, where there is one favourable and one unfavourable season, may be exemplified by desert climates like those of the Northern Sudan or Mesopotamia. In both countries the winter is bracing and pleasant, and in both the long and trying summer is hot as Tophet. Hence it is not surprising that the former has been described as a country where white women lose their looks and white men their energy.

Speaking broadly, the seasonal changes of a tropical climate, if at all marked, are beneficial rather than otherwise. It is tropical weather that is to blame, and it is at fault because it has not the characteristics of what we call weather in this country. There is far too much climate and far too little weather in the tropics. One is reminded of the schoolboy's essay on marriage customs wherein he spoke of the state of having one wife which, according to him, is called "monotony." The simile is not a bad one, for in both cases the even tenor of existence may be punctuated by storms!

From what has been said it must be clear that an equability of temperature, a powerful sun, and a high degree of atmospheric humidity are the climatic factors which in the moist tropics at least militate against the comfort and well-being of the white settler. In the dry tropics, excessive dryness of the air, together with sun and heat, is operative, and this combination is frequently associated with electrical states of the atmosphere which may conceivably play a much more important rôle than has hitherto been attributed to them. Whether that rôle, however, is deleterious or the reverse remains to be decided. It may be a cause of mental irritability. On the other hand, it may exercise a beneficial, stimulating effect. Kullmer,[10] an American geographer, was inclined to think that possibly electrical phenomena accompanying the barometric changes which induce storms had much to do with the advancement of civilisation. It is conceivable that the comparative innocuousness of desert climates in the tropics is due to the frequency and force of electric disturbances. The air at times becomes very highly charged, and it is astonishing how a blanket on the slightest movement will crackle and spark. I would suggest that this is a line of investigation well worth pursuing. Considering the amazing electrical developments of late years, who can say that such a study might not lead to the discovery of methods whereby the stimulating and rejuvenating action of electricity might not be utilised to counteract the depressing influence of a hot and humid climate? In such climates the effects of a severe thunderstorm are often remarkable. I recall a suffocating night on the Magdalena River in Colombia when one could scarcely breathe, so great was the oppression of the atmosphere, and the remarkable change produced in half an hour by a violent outburst of electricity.

PSYCHOLOGICAL EFFECTS.

Whatever the factors at work, the effects they produce may be classed as physiological, psychological, and pathological. Of these the greatest are the psychological, for Cuvier's axiom, already quoted, must ever be borne in mind. The psychological effects are purely subjective and we are always conscious of them, which is by no means invariably the case as regards the physiological, and yet, though in many cases no proof can be advanced, the psychological effects are probably in every instance based upon physiological change. At any rate, it is better not to try and divorce them, but to consider the psychological effects as part of the physiological effects on the nervous system. It is true that these latter effects may be associated with psychological results, without there being any direct action on the nervous system, for the change may be induced in the circulatory or other apparatus, but the expression of the psychological effects must needs be through the brain. Although a consideration of the effects of a tropical climate on the individual may not supply data for determining the influence it will exert upon the white race viewed in the light of colonisers, yet this aspect of the subject cannot be wholly neglected. Indeed, it furnishes the greater part of the scientific evidence on which any conclusions can at present be formed. Unfortunately, the evidence is conflicting and far from being complete. I do not propose to discuss all the work that has been done on the physiological and pathological effects of tropical climates. It seems wiser, considering the magnitude of the subject, to refer very briefly to some of the more important observations made in the past and then to concentrate on recent contributions to the literature, commenting, where it seems desirable, on the statements and views which have been advanced and confining myself as much as possible to the hygienic aspect of the question.

BODY TEMPERATURE.

Naturally considerable attention has been directed to body temperature, but the earlier records leave much to be desired owing to the conditions under which the observations were made. There seems

PROBLEMS OF ACCLIMATISATION.[*]

BY ANDREW BALFOUR, C.B., C.M.G.,
M.D., F.R.C.P. EDIN.,
DIRECTOR-IN-CHIEF, WELLCOME BUREAU OF SCIENTIFIC RESEARCH, LONDON.

THE preceding lecture was devoted to a somewhat comprehensive though by no means exhaustive account of intentional or unintentional white settlements in the tropics, and to a consideration of the various and varying views which have been advanced regarding such efforts at colonisation. There still remains, however, one important point which must not be forgotten, and that is the influence of altitude in modifying the climatic effects of a country in the tropic zone.

TROPICAL HIGHLANDS.

Kenya is much in the public eye at present and, so far as the British Empire is concerned, Kenya is the colony specially interested in this question. Unfortunately it is not one which can readily be answered. We know, of course, that in a climate like that of the East African highlands many Europeans can and do lead active and energetic outdoor lives. It is possible that, if native labour was not forthcoming, they could with impunity, so far as health is concerned, undertake the work which now falls to the lot of the Kikuyu and other sons of Ham. It has, indeed, been suggested that the European might labour like the native provided he knocked off work during the hot hours—i.e., from 10 A.M. to 3 P.M. This, however, would make a very short working day, which, I understand, would not satisfy the needs of the agriculturist.

The children, despite statements to the contrary, do well. I remember during the war attending a children's party at Government House, Nairobi, and being struck by the fitness and high spirits of the youthful guests. Save for the fact that they were somewhat pale, they would have compared favourably with a similar gathering of youngsters in this country. Moreover, a few children born in the colony have attained adult life and appear to be healthy and vigorous men and women. It must, however, be remembered that it is not merely a question of bodily health and energy. A weakening of will power is one of the first tokens that a hot climate is beginning to tell upon an individual and it manifests itself, as Huntington points out, in many ways, but chiefly along four lines—namely, lack of industry, irascibility of temper, drunkenness, and excess in venery. As we view the past and as the future unrolls, it will be interesting to see if some or any of these failings are in evidence, not only in the Kenya highlands, but elsewhere amongst European communities who have settled in tropical uplands. If such traits do make their appearances it will be well to recall the fact that while, as ever, several factors are concerned, climate may be playing an insidious but none the less definite part in lessening restraint. Speaking generally, the white population of Kenya is industrious and has faced manifold difficulties in a gallant manner, but it is a question if, as the long years pass, there will not be seen a tendency towards slackness, especially perhaps when the stimulus of rapid development has somewhat abated. Still, these are early days and there are scarcely any scientific data on which to base an opinion.

Steudel,[1] it is true, states that in the case of Europeans living in tropical highlands changes occur in the nervous system, if not in the first certainly in the second and subsequent generations. Indeed, he records the presence of neurasthenia amongst Germans who had been living at high altitudes in what is now known as Tanganyika territory. Naturally the altitude itself, provided it be considerable, complicates the question. The matter lies outside the scope of this lecture, but those interested may with advantage consult Hingston's[2] paper as regards India, and that of Ocaranza[3] who deals with Mexico. Meyer[4] has also considered the subject, so far as the blood picture is concerned, while Mackinnon[5] commenced a research at Nairobi on the cardiac condition in children. It is unfortunate that he was unable to continue his inquiries, but he has recently published an interesting paper[6] on education in its relation to the physical and mental development of European children of school age in Kenya. He finds that the warmth and light exercise a stimulating and salutary effect on growth, at least when the food conditions are satisfactory. Both as regards height and weight the Kenya children compare favourably with English children of the same age and presumably, though he does not say so, of the same social class. At first, also, there is a quickening of mentality. In fact, all goes well until the age of 10 years is reached, but thereafter a gradual process of mental exhaustion and deterioration supervenes, which appears especially to affect the memory and the power of application. So much is this the case that he considers that the Government would be well advised to limit any scheme for secondary education to such children as cannot be sent out of the country, and should, by establishing scholarships and providing monetary grants, enable children after the age of 10 to be despatched to the home country for the completion of their education. Here, then, there would appear to be definite evidence of the deleterious effect of climate upon the developing nervous system. Kohlbrugge,[7] also, with a long experience of Java, considers that a tropical mountain climate is very deleterious to the nervous system of Europeans. Altitude is said to be beneficial rather than harmful, as it favours lung expansion and increases the number of the red blood cells.

STIMULATING POWER OF CHANGEABLE CLIMATE.

So far as Kenya is concerned, if we put aside any possible influence which may be exerted by the native races or the immigrant East Indians, the future of the white race inhabiting its high plateaus would appear to depend on whether or not its climate has sufficient stimulating power. Now what are the attributes which confer upon a climate powers of stimulation? Moderate changes of temperature from one day to the next play a great part—indeed, it would seem a greater part than relative humidity, though the degree of humidity is important. It should, however, be noted that Schilling,[8] a German authority on the subject, is of opinion that an equable temperature is only deleterious because it is almost always associated with a high degree of atmospheric humidity. Be that as it may, there is no doubt that the ideal climate is characterised by moderate changes with air cooling at frequent intervals. According to Huntington,[9] mental activity reaches a maximum when the outside temperature averages about 38°, that is when there are mild frosts at night. Huntington also lays great stress on the influence of storms and, from a study of history, shows how climatic changes occurred in certain regions of the world, how such changes consisted primarily of a shifting of the belt of storms, how countries like China, Mesopotamia, Palestine, and Egypt, which in the olden days lay within the storm belt, possessed great civilisations and intelligent and vigorous people, and how, with a change of climate, there was retrogression. His "pulsatory hypothesis" of climate, as he terms it, signifying that changes have taken place irregularly in great waves, is certainly well worthy of consideration, as is the theory he has evolved from it, even if he finds it difficult to explain on his hypothesis the ancient culture of Indo-China and Ceylon. We cannot, however, follow him further in his argument; reverting to Kenya, it may be said that while limited portions of the high tablelands would appear to be blessed with climatic conditions which should suffice for purposes of stimulation, it is, to say the least, doubtful if this can be predicated of the whole elevated area over which white settlers are scattered, and more especially of Nairobi and its immediate neighbourhood. Still, only time can show, and it should be remembered that we do not yet know if marked changes in the 24 hours as, say, between the day and night temperature or even considerable diurnal variations, can make up for the differences of season as experienced in temperate lands. The future is, as it were, upon the knees of the gods and, as we shall see, there may yet be developments which will modify the climate or enable men to defy it.

[*] The second of a series of lectures, delivered at St. Bartholomew's Hospital on June 14th under the auspices of the Academic Council of the University of London. The first lecture appeared in THE LANCET of June 30th.

CLIMATE AND HUMAN METABOLISM.

Having considered the broader aspects of this question of the influence of tropical climate upon the white races of mankind it is time to discuss its effect on human metabolism in more detail. Huntington likens the influence of climate upon men to that of a driver upon his horse, and the simile is both homely and apt. He says:—

> "Some drivers let their horses go as they please. Now and then a horse may run away, but the average pace is slow. Such drivers are like an unstimulating climate. Others whip their horses and urge them to the limit all the time. They make rapid progress for a while, but in the end they exhaust their animals. They resemble climates which are always stimulating. In such climates nervous exhaustion is likely to prevail and insanity becomes common. A third type of drivers first whip their horses to a great speed for a mile or two, and then let them walk slowly for another mile or two. They often think that they are accomplishing great things, and they are better off than the two types already mentioned, but they still have much to learn. They are like a climate which has a strong contrast of seasons, one being favourable and the other unfavourable. Still a fourth kind of driver may whip his horse sometimes and sometimes let him walk, but what he does chiefly is to urge the animal gently with his voice, then check him a little with the rein. By alternate urging and checking he conserves the animal's strength, and in the long run can cover more distance and do it more rapidly than any of the others. Such a driver resembles a climate which has enough contrast of seasons to be stimulating but not to create nervous tension, and which also possesses frequent storms whose function is to furnish the slight urging and checking which are so valuable in the total effect, although each individual impulse is almost unnoticeable."

Now, save as regards the fourth type, which cannot be said to exist in the tropics, it is possible to cite countries within the torrid zone furnishing examples of these varieties of climate. The first, the unstimulating, is that met with along tropical littorals, as, for example, the West Coast of Africa, in great forests like those of the Amazon, or in islands like most of the West Indies or the Polynesian archipelago. The second type, producing over-stimulation, can be found only at high altitudes such as exist in the Andes. Parts of Peru—as, for instance, the region of Cuzco—may be cited. The third type, where there is one favourable and one unfavourable season, may be exemplified by desert climates like those of the Northern Sudan or Mesopotamia. In both countries the winter is bracing and pleasant, and in both the long and trying summer is hot as Tophet. Hence it is not surprising that the former has been described as a country where white women lose their looks and white men their energy.

Speaking broadly, the seasonal changes of a tropical climate, if at all marked, are beneficial rather than otherwise. It is tropical weather that is to blame, and it is at fault because it has not the characteristics of what we call weather in this country. There is far too much climate and far too little weather in the tropics. One is reminded of the schoolboy's essay on marriage customs wherein he spoke of the state of having one wife which, according to him, is called "monotony." The simile is not a bad one, for in both cases the even tenor of existence may be punctuated by storms!

From what has been said it must be clear that an equability of temperature, a powerful sun, and a high degree of atmospheric humidity are the climatic factors which in the moist tropics at least militate against the comfort and well-being of the white settler. In the dry tropics, excessive dryness of the air, together with sun and heat, is operative, and this combination is frequently associated with electrical states of the atmosphere which may conceivably play a much more important rôle than has hitherto been attributed to them. Whether that rôle, however, is deleterious or the reverse remains to be decided. It may be a cause of mental irritability. On the other hand, it may exercise a beneficial, stimulating effect. Kullmer,[10] an American geographer, was inclined to think that possibly electrical phenomena accompanying the barometric changes which induce storms had much to do with the advancement of civilisation. It is conceivable that the comparative innocuousness of desert climates in the tropics is due to the frequency and force of electric disturbances. The air at times becomes very highly charged, and it is astonishing how a blanket on the slightest movement will crackle and spark. I would suggest that this is a line of investigation well worth pursuing. Considering the amazing electrical developments of late years, who can say that such a study might not lead to the discovery of methods whereby the stimulating and rejuvenating action of electricity might not be utilised to counteract the depressing influence of a hot and humid climate? In such climates the effects of a severe thunderstorm are often remarkable. I recall a suffocating night on the Magdalena River in Colombia when one could scarcely breathe, so great was the oppression of the atmosphere, and the remarkable change produced in half an hour by a violent outburst of electricity.

PSYCHOLOGICAL EFFECTS.

Whatever the factors at work, the effects they produce may be classed as *physiological*, *psychological*, and *pathological*. Of these the greatest are the psychological, for Cuvier's axiom, already quoted, must ever be borne in mind. The psychological effects are purely subjective and we are always conscious of them, which is by no means invariably the case as regards the physiological, and yet, though in many cases no proof can be advanced, the psychological effects are probably in every instance based upon physiological change. At any rate, it is better not to try and divorce them, but to consider the psychological effects as part of the physiological effects on the nervous system. It is true that these latter effects may be associated with psychological results, without there being any direct action on the nervous system, for the change may be induced in the circulatory or other apparatus, but the expression of the psychological effects must needs be through the brain. Although a consideration of the effects of a tropical climate on the individual may not supply data for determining the influence it will exert upon the white race viewed in the light of colonisers, yet this aspect of the subject cannot be wholly neglected. Indeed, it furnishes the greater part of the scientific evidence on which any conclusions can at present be formed. Unfortunately, the evidence is conflicting and far from being complete. I do not propose to discuss all the work that has been done on the physiological and pathological effects of tropical climates. It seems wiser, considering the magnitude of the subject, to refer very briefly to some of the more important observations made in the past and then to concentrate on recent contributions to the literature, commenting, where it seems desirable, on the statements and views which have been advanced and confining myself as much as possible to the hygienic aspect of the question.

BODY TEMPERATURE.

Naturally considerable attention has been directed to body temperature, but the earlier records leave much to be desired owing to the conditions under which the observations were made. There seems

PROBLEMS OF ACCLIMATISATION.*

BY ANDREW BALFOUR, C.B., C.M.G.,
M.D., F.R.C.P. EDIN.,
DIRECTOR-IN-CHIEF, WELLCOME BUREAU OF SCIENTIFIC
RESEARCH, LONDON.

THE preceding lecture was devoted to a somewhat comprehensive though by no means exhaustive account of intentional or unintentional white settlements in the tropics, and to a consideration of the various and varying views which have been advanced regarding such efforts at colonisation. There still remains, however, one important point which must not be forgotten, and that is the influence of altitude in modifying the climatic effects of a country in the tropic zone.

TROPICAL HIGHLANDS.

Kenya is much in the public eye at present and, so far as the British Empire is concerned, Kenya is the colony specially interested in this question. Unfortunately it is not one which can readily be answered. We know, of course, that in a climate like that of the East African highlands many Europeans can and do lead active and energetic outdoor lives. It is possible that, if native labour was not forthcoming, they could with impunity, so far as health is concerned, undertake the work which now falls to the lot of the Kikuyu and other sons of Ham. It has, indeed, been suggested that the European might labour like the native provided he knocked off work during the hot hours—i.e., from 10 A.M. to 3 P.M. This, however, would make a very short working day, which, I understand, would not satisfy the needs of the agriculturist.

The children, despite statements to the contrary, do well. I remember during the war attending a children's party at Government House, Nairobi, and being struck by the fitness and high spirits of the youthful guests. Save for the fact that they were somewhat pale, they would have compared favourably with a similar gathering of youngsters in this country. Moreover, a few children born in the colony have attained adult life and appear to be healthy and vigorous men and women. It must, however, be remembered that it is not merely a question of bodily health and energy. A weakening of will power is one of the first tokens that a hot climate is beginning to tell upon an individual and it manifests itself, as Huntington points out, in many ways, but chiefly along four lines—namely, lack of industry, irascibility of temper, drunkenness, and excess in venery. As we view the past and as the future unrolls, it will be interesting to see if some or any of these failings are in evidence, not only in the Kenya highlands, but elsewhere amongst European communities who have settled in tropical uplands. If such traits do make their appearances it will be well to recall the fact that while, as ever, several factors are concerned, climate may be playing an insidious but none the less definite part in lessening restraint. Speaking generally, the white population of Kenya is industrious and has faced manifold difficulties in a gallant manner, but it is a question if, as the long years pass, there will not be seen a tendency towards slackness, especially perhaps when the stimulus of rapid development has somewhat abated. Still, these are early days and there are scarcely any scientific data on which to base an opinion.

Steudel,[1] it is true, states that in the case of Europeans living in tropical highlands changes occur in the nervous system, if not in the first certainly in the second and subsequent generations. Indeed, he records the presence of neurasthenia amongst Germans who had been living at high altitudes in what is now known as Tanganyika territory. Naturally the altitude itself, provided it be considerable, complicates the question. The matter lies outside the scope of this lecture, but those interested may with advantage consult Hingston's[2] paper as regards India, and that of Ocaranza[3] who deals with Mexico. Meyer[4] has also considered the subject, so far as the blood picture is concerned, while Mackinnon[5] commenced a research at Nairobi on the cardiac condition in children. It is unfortunate that he was unable to continue his inquiries, but he has recently published an interesting paper[6] on education in its relation to the physical and mental development of European children of school age in Kenya. He finds that the warmth and light exercise a stimulating and salutary effect on growth, at least when the food conditions are satisfactory. Both as regards height and weight the Kenya children compare favourably with English children of the same age and presumably, though he does not say so, of the same social class. At first, also, there is a quickening of mentality. In fact, all goes well until the age of 10 years is reached, but thereafter a gradual process of mental exhaustion and deterioration supervenes, which appears especially to affect the memory and the power of application. So much is this the case that he considers that the Government would be well advised to limit any scheme for secondary education to such children as cannot be sent out of the country, and should, by establishing scholarships and providing monetary grants, enable children after the age of 10 to be despatched to the home country for the completion of their education. Here, then, there would appear to be definite evidence of the deleterious effect of climate upon the developing nervous system. Kohlbrugge,[7] also, with a long experience of Java, considers that a tropical mountain climate is very deleterious to the nervous system of Europeans. Altitude is said to be beneficial rather than harmful, as it favours lung expansion and increases the number of the red blood cells.

STIMULATING POWER OF CHANGEABLE CLIMATE.

So far as Kenya is concerned, if we put aside any possible influence which may be exerted by the native races or the immigrant East Indians, the future of the white race inhabiting its high plateaus would appear to depend on whether or not its climate has sufficient stimulating power. Now what are the attributes which confer upon a climate powers of stimulation? Moderate changes of temperature from one day to the next play a great part—indeed, it would seem a greater part than relative humidity, though the degree of humidity is important. It should, however, be noted that Schilling,[8] a German authority on the subject, is of opinion that an equable temperature is only deleterious because it is almost always associated with a high degree of atmospheric humidity. Be that as it may, there is no doubt that the ideal climate is characterised by moderate changes with air cooling at frequent intervals. According to Huntington,[9] mental activity reaches a maximum when the outside temperature averages about 38°, that is when there are mild frosts at night. these hot and arid regions, and renders them less trying, in the long run, than the humid tropics.

Probably of greater importance than the question of changes in the formed elements of the blood and the hæmoglobin is that of its chemical or physico-chemical constitution, though here we are on debatable ground. A consideration of the scanty literature on the subject emphasises the pressing need for bio-chemical work in the tropics. The bacteriologist, the protozoologist, the pathologist, and even the epidemiologist, have all thrown light upon tropical hygiene, but, with some notable exceptions, the physiologist, and more especially the bio-chemist, has not yet come into his own in this realm of research. I was sorry to see that some time ago the proposal to attach a bio-chemist to the staff of the London School of Tropical Medicine was negatived. His help would have been valuable even in this country, but there is a great field for him abroad, more especially in the direction of blood work. The Dutch, who are very much to the fore in all matters pertaining to tropical hygiene, have been quick to realise the importance of bio-chemistry in their tropical possessions. De Langen and Schut[25] [26] estimated the sugar content of the blood in native Javans and Europeans and in rabbits, guinea-pigs, and hens in Java. In all it was high, and in the case of Europeans and of the animals considerably higher than is the case in Europe. This hyperglycæmia is almost certainly associated with a deficiency in calcium and a reduction in the cholesterin of the blood. The Dutch observers ascribe the condition to heat. Humidity, it is said, may also play a part by stimulating the sympathetic nervous system which regulates the function of the suprarenal glands. The hepatic glycogen is no longer stored up as usual, the sugar content of the blood increases, and an attempt is made to throw off this excess of sugar in the circulating blood. It is eliminated through the kidneys, the so-called renal glycosuria, or is burned up. To the latter event is ascribed the "low fever" of the tropics which, if the Dutchmen are correct, has a climatic, not a parasitic cause. As hyperglycæmia disposes to neuritis and polyneuritis and favours invasion by the tubercle bacillus it will be seen that this research has an important bearing on the subject we are discussing. The condition cannot be the same as the *hyperglycæmia* observed by McCay[27] in Bengal, and which he attributed to excessive carbohydrate diet, for it appears soon after the arrival of Europeans in the tropics.

De Langen and Schut[28] have also investigated the fat content of the blood. A reduction in cholesterin has already been mentioned, and two-thirds of the blood-fat is cholesterin. The total fat content is somewhat higher in Europeans than in natives. It would take us too far afield to consider all their findings and deductions, but it may be said that the matter may have important bearings on diet in the tropics, for the blood lipoids which constitute the fat core proper—that is, the finely emulsified fat present in the serum either in a colloidal or invisible form—would appear to be intimately concerned with cell life and function. The difference in the cholesterin content of the blood of natives and Europeans was not thought to be wholly due to differences in diet. De Langen[29] invoked a special function of the endocrine glands to explain it, while Verhoef[30] was inclined to attribute it to climate. Now, however, it would seem that de Langen[31] has revised his views and is prepared to put down the low cholesterin content, in native convicts at least, to a scarcity of fat in the diet. The matter is still sub judice, and I only mention it as showing how much we are in the dark as regards these difficult but suggestive problems. The percentage of water in the blood of healthy individuals in the tropics has been shown to be practically the same as that of Europeans at home—i.e., 78·6 per cent.

So far as *circulatory change* is concerned the observations are very contradictory. I would therefore merely mention that the Australian workers at Townsville[12] found that humid heat produced a rise both in blood pressure and pulse-rate, while de Jonge,[32] working in the Dutch East Indies, maintains that the maximum blood pressure of Europeans does not diminish as the result of prolonged tropical residence.

Digestion and Excretion.

A hot climate at first stimulates digestion and the digestive functions, but the effect is evanescent, being soon followed by a diminution in appetite and some lowering of digestive activity, with an accompanying lessened desire for animal food. It is interesting to note that recent American experiments on dogs show that in hot weather the secretion of bile may strikingly diminish even if the food intake remains considerable.

The urinary excretion is diminished in the tropics, the daily output being about 500 to 700 c.cm., as against 1500 in temperate regions. The urine is concentrated, but it is a moot question whether or not it contains an equal amount of waste material to that found in the 1500 c.cm. Some say one thing, some another. Young,[33] in North Queensland, found the neutral sulphur content high, but was unable to say whether or not this was due to increased tissue metabolism. He noted a much higher specific gravity of the urine,[34] a diminution in the quantity of sodium chloride excreted and a lessening of the total nitrogen.

McCay,[35] in Bengal, did much work on Asiatics; but of more importance for our purpose are the observations of Campbell[36] in Singapore, a place where there is no cool season and the temperature averages 80° F. all the year round. There he found that race had no influence on the nitrogen partition and that for a European, a Eurasian, and several races of Asiatics alike the absolute quantities of total nitrogen, of urea nitrogen, and of uric-acid nitrogen were much lower than the standard figures for Europe. On the other hand, the percentages of urea nitrogen and uric-acid nitrogen did not materially differ from the standard, while the percentage of ammonia nitrogen was increased and absolute ammonia nitrogen was also often increased. McCay[27] did not estimate the creatinin nitrogen, dealing only with neutral sulphur. Campbell found the amount to be slightly lower than the European standard but the percentage higher.

In a Chinese, a European, and a Eurasian the total nitrogen per kilo of weight proved to be about the same as the standard. In other races it was lower. Campbell attributed the low results to the indirect effects of heat and humidity which lessen the desire for food and work, thus leading to poor physique and less muscular energy. This may be true in the case of the European and the Eurasian, but recent work by Read and Wang[37] at Peking in China, at a time when the weather was dry and cold, work carried out on Chinese and yielding results comparable with those of McCay, Campbell, and Young, would *seem to show that* the differences noted are entirely due to diet. In other words, an exogenous rather than an endogenous factor is at work, and the high cereal diets are probably the cause.

(*Continued at foot of next page.*)

however, now to be a general agreement that when one passes from a temperate to a tropical climate a slight rise of body temperature, rarely exceeding 1·5° F. occurs, while after arrival in the tropics the body temperature of the newcomer tends to remain slightly elevated. Adjustment of temperature, however, soon takes place in most cases, though there are certain individuals, obviously unfitted for tropical life, who do not possess the power of adaptation. Caspari and Schilling,[11] who carried out some interesting comparative experiments on metabolism in Germany and the West Coast of Africa, found that an ordinary and well-balanced diet had no influence on body temperature either in the acclimatised or non-acclimatised European. Neither has moderate exercise, but, according to Young, Breinl, Harris, and Osborne,[12] who conducted investigations in North Queensland, prolonged exercise does cause a rise of temperature even in acclimatised persons. It is important to take the temperature in the rectum, not in the mouth or axilla. As Leonard Hill[13] has pointed out, atmospheric conditions in the tropics undoubtedly impose a strain on the heat-regulating mechanism of the body. Hence the very effort to keep the temperature normal tends towards exhaustion, and unfavourable conditions of diet and clothing, at least when combined with considerable or severe exercise, raise the body heat.

SKIN REACTION.

Closely associated with the question of body temperature is that of skin reaction, because the regulation of body temperature is secured by the evaporation of water from the surface of the body as well as from the lungs. Aron,[14] in Manila, showed that the brown-skinned man possesses a more sensitive cutaneous heat-regulating apparatus than his white brother. This is presumably due in the first instance to colour, as brown skin absorbs more heat than white skin and hence more rapidly, as the result of nerve stimulation, the stage is reached when perspiration shows itself. Moreover, brown skin cools more rapidly than white skin. On this account, as well as for other reasons, tanning of the white skin is beneficial and the lack of it is doubtless, in part, a cause of the poor adaptability to heat which the white woman who lives indoors or carefully guards her complexion usually displays.

I have spoken about brown skin absorbing heat. What really happens is that the light rays pass through the cutis till they strike the pigment layer where they are converted into heat. In the case of the white skin the light rays pass right through and the conversion into heat takes place as the result of the action of the blood pigment. A thin skin is a useful asset in promoting conduction, for the horny layer is a very bad conductor of heat. The brown or black man, protected by his pigment, does not require a thick, horny layer, but it is significant that Priestley [15] has noted a coarsening of the skin of white women in tropical Australia. Had these women done field work their skins might have become tanned instead of thickened. Of two evils it were well to choose the lesser. Persons who do not perspire or who have a defective sudorific system are unsuited to residence in the tropics, and in the case of prospective settlers inquiry should always be made on this point. A defect of this kind may be transmitted to the offspring.

RESPIRATORY EXCHANGE.

Little need be said about respiratory exchange. The lungs, which by the evaporation of water from them aid the cooling process, weigh less in hot than in cold or temperate climates, because the place of the blood which passes to the warm body surface is taken by air. Pulmonary capacity is therefore increased, but the lessened number of respirations preserves the necessary balance. In the tropics the air which is inhaled is rarefied by heat and so contains less oxygen than cold air. The respirations being reduced in number and less oxygen inspired, less carbonic acid and water vapour are given off by the lungs. As a result there is a tendency to the retention of carbonaceous matter in the blood. So far as I can discover, no ill-effects have been attributed thereto, but it is conceivable that it may tend towards fatigue. Young[12] and his co-workers showed that the alveolar air at rest in inhabitants of tropical Queensland exhibited a lower carbon dioxide content than the European average.

BLOOD.

The blood is the life, and, as might be expected, numerous observations have been made in various parts of the world on the blood state of Europeans in the tropics. It is possible that they began with those of Mayer carried out at Java in 1840, when on bleeding his patients he noticed that their venous blood was much redder than he had found it when venesecting in Germany. His deductions from this phenomenon, however, concern basal metabolism, and will be considered later. There is some doubt as to whether climate alone can produce any change in the formed elements of the blood. There is no certain evidence that it produces anæmia, the pallor of old tropical residents being merely skin deep, due to a local vasomotor condition, a cutaneous ischæmia, as Musgrave and Sison[16] maintain. Certainly, so far as the Philippines are concerned, Chamberlain[17] has shown that the blood of white men after a year or more of residence is well up to standard. On the other hand, Mitchell,[18] a British naval surgeon, declares that the damp heat of the Persian Gulf produced a simple but severe anæmia in cases under his care. Unfortunately, he gives no blood counts, although he states that the blood was examined. His conclusions are not convincing.

It is possible that climate may produce changes in the hæmoglobin. Thus Plehn,[19] working in the Cameroons, found evidence of hæmoglobinæmia, while Gibbs,[20] in Manila, showed that ultra-violet light can transform oxyhæmoglobin into methæmoglobin. According to Harston[21] the blood of children in the tropics shows a diminution in the percentage of hæmoglobin, though the red cells are increased relatively to the fluid elements of the blood, because the latter is more concentrated owing to excessive perspiration. He considers the lessened hæmoglobin content to be due to: (1) The fact that heated air contains less oxygen per cubic foot than cool air; (2) the slower respiratory exchange to which reference has already been made; (3) the depletion of blood in the lungs which has also been mentioned.

Some sound work was carried out not long ago by Kop,[22] who, at Weltevreden in Java, investigated the blood of 93 normal healthy individuals—55 Europeans and 38 natives. The blood counts were made on films taken with due precautions before 9 o'clock in the morning from subjects with empty stomachs. In each case the red and white corpuscles were enumerated, the hæmoglobin index was determined, a differential leucocyte count performed, and the Arneth index noted. No difference of any kind was found between the blood of these people and that of dwellers in temperate climates, save that the natives had eosinophilia, doubtless due to infection with intestinal worms. Elsewhere a shift to the left in the Arneth count has been described, possibly indicating a lowered resistance to disease, but the records are not very satisfactory, and in all likelihood Kop's results are generally applicable. The lymphocytosis which has occasionally been observed is probably a pathological symptom not due to climate. It must, however, be noted that observations in the Egyptian deserts by Bickel, Loewy, and Wohlgemuth,[23] and amongst the Djerids of South Tunis by Grober[24] have conclusively shown that under the peculiar climatic conditions obtaining in these regions there is an increase in the erythrocytes and hæmoglobin. It has been suggested that the peculiar and intensive light conditions prevailing in the desert stimulate the blood-forming organs, just as experimentally the light of a mercury lamp induces in them a fresh activity resulting in red cell increase. It is conceivable that such a stimulant action mitigates the ill-effects of

OPEN-AIR TREATMENT OF SURGICAL TUBERCULOSIS.

A VISIT TO ALTON.

THE vice-presidents, companions, and local honorary secretaries of the Queen Alexandra League were entertained by Sir William Treloar at Alton, Hants, on July 4th, on the occasion of the visit of Sir Clifford Allbutt. Sir William Treloar, before introducing Sir Clifford Allbutt, stated that the League was founded 17 years ago by Queen Alexandra for the purpose of collecting money for the Lord Mayor Treloar Cripples' Hospital and College, and during last year had raised over £9000.

Address by Sir Clifford Allbutt.

Sir Clifford Allbutt, after expressing his great pleasure at having this opportunity of seeing the remarkable work in progress at Alton, quoted Sir Anthony Bowlby as saying that the glory of Alton had abated surgery and that the old treatment of excision of joints had passed into oblivion. He gave a brief outline of the progress of medical knowledge in respect to tuberculosis, recalling the coddling treatment of this disease when even the keyholes were stuffed with cotton-wool in order to lessen the possibility of a draught reaching the patient. Tuberculosis, spread by infection, was a general disease, therefore local excision was not the best treatment. The value of open air, good food, and above all sunlight as means to increase the natural resistance was very potent. He stressed the importance of precise dosage and careful distribution in sunlight treatment in order that perils should be avoided and successes won. From Hippocrates onwards the law of reciprocal action, the ability of Nature to hit back, had been continually demonstrated. The intrinsic natural reaction of the individual was often strong enough to withstand infection. Open air increased the fortifications of the physiological reactions and replaced natural exercise in keeping the patient healthy. Alton was fortunate in having a pavilion with 50 beds at Hayling Island. Sir Clifford Allbutt paid a tribute to Rollier for his work in heliotherapy and occupation therapy; at Alton 14 teachers and four technical instructors were employed to keep the patients happily occupied. To the importance of early treatment and the value of following up cases after discharge he largely attributed the successful results, exclusive of accidents, in 95 per cent. of the cases sent to Alton. Sir Clifford Allbutt concluded by stating the two modern events which had given him the greatest pleasure—the remarriage of surgery with internal medicine after their long divorce, and the formation of an institute of comparative medicine at Cambridge.

The Work at Alton.

The work at Alton is too well known to need detailed description. Amongst its many interesting features may be mentioned the observation ward where each new patient admitted is kept for a period of at least a fortnight in quarantine. Each child occupies a separate cubicle and during his stay the case is worked up, his educational standard ascertained, X rays taken, and necessary splints manufactured. After that the patient is warded—or rather gradually acclimatised to open air and sunlight—not according to age or medical classification, but according to his standard of intelligence and school class. Non-inflammable perforated celluloid plasters and various splints and methods of extensions invented at Alton are in use with remarkable results. The difference in degree of pigmentation was considerable, every child having an individual reaction to sunlight. The red-haired, much freckled white-skinned type are unable to tolerate exposure and have consequently a less hopeful prognosis. The beds in the "*Hampshire*" ward are heated electrically, Alton being the first hospital to adopt this method. In sharp contrast to cases of surgical tuberculosis as seen in a general hospital or out-patient department is the total absence of muscular wasting. This is attributed to the action of open air on the skin—a loin cloth and sun hat is generally the only covering. The effect of fresh air on naked skin has been proved by Dr. Leonard Hill, Dr. Argyll Campbell, and Sir Henry Gauvain to increase greatly the metabolism of the body. It is stated that the pigmented patients at Alton, even though suffering from surgical tuberculosis, have their working capacity increased on an average by 37 per cent. beyond that of normal healthy children.

Alton is a striking example of what a hospital, situated in ideal country surroundings, supplying its own vegetables, fruit, pigs, and eggs can do for its patients.

MEDICINE AND THE LAW.

LIABILITY FOR IMPURE WATER-SUPPLY.

AFTER litigation extending over two years the High Court of California, U.S.A., has recently awarded substantial damages, to be paid by the city authorities, to 19 persons who contracted typhoid fever at Pittsburgh, in consequence of a breakdown in the apparatus for purifying the city's water-supply. This is drawn from the Sacramento river, the water of which is recognised as unfit for drinking until properly treated, and at a date preceding the outbreak of typhoid, from which the plaintiffs suffered, the chlorinating plant was for a time inoperative owing to the fixtures upon a drum containing chlorine gas not permitting of its attachment to the pumping system until the necessary alteration of the fittings had been made. The court has held that an obligation lies upon the city authorities who distribute the water to use all reasonable precaution to render it fit and wholesome. Presumably, in terms familiar in our courts, the judgment was to the effect that there was negligence in not securing a supply of chlorine gas in a receptacle suitable for use in the machinery installed for the purpose, and in allowing water to be supplied in a condition known to be unsafe, and without warning to the public. Subject to any special provision not likely to be inserted in any water company's Act, there can be no reason why such an action should not lie in this country in similar circumstances.

AUTHORITY TO ENGAGE AN AMBULANCE.

At Romford County Court recently his honour Judge Crawford tried an unusual action, in which the Romford Urban Council sued a Mr. Thwaites for payment for the use of the town ambulance to convey him to a London hospital. Mr. Thwaites denied liability and said that he could have travelled by omnibus or similar conveyance, and that the ambulance had been ordered by his medical attendant, Dr. V. Levy, without his authority. Accordingly the Council had joined Dr. Levy as a defendant and he was represented at the trial by Mr. H. F. Dickens, briefed by the solicitor to the Medical Defence Union. As to the main facts there was no dispute. Dr. Levy had attended Mr. Thwaites, who was suffering from severe abdominal pains, and on receiving a second summons decided that the case was one of urgency, and accordingly, on his way to his *patient's house*, asked for an ambulance to be sent at once to take him to a hospital. He told the court that he would have been running a great risk if he had allowed any delay to occur. On Mr. Thwaites saying that he could have travelled in an omnibus or tram-car Judge Crawford asked, "Don't you think that the doctor was the best judge of that?" In giving his decision, Judge Crawford compared the case to that of the captain of a ship who when out of reach of his owners had to come to a decision and take responsibility *on their behalf*. A doctor in a similar case of great urgency became, in his opinion, an "agent by necessity" and was fully justified in taking whatever steps he might think necessary in his patient's

NATIONAL BABY WEEK CONFERENCE.

(Continued from p. 33.)

The subject under discussion on the morning of July 3rd was the

Scope, Staffing, and Administration of an Infant Welfare Centre,

the points for consideration being well set out in an introductory speech by Mr. H. O. Stutchbury, the chairman. In regard to staff, the Ministry of Health had an open mind as to the relative values of a whole-time medical officer appointed by the local authority, a specialist in child welfare, and a general practitioner, always provided that the doctor had special knowledge of children's health. A medical officer doing nothing but children's work was apt to suffer from monotony, and there was, he thought, little to be said in favour of a rota of doctors, as continuity in advice and treatment must necessarily be lost.

Dr. W. G. Willoughby considered that it came within the scope of a welfare centre to procure or provide medical treatment for cases in which treatment was unlikely to be obtained otherwise. If the medical part of child welfare was universally carried out by private practitioners, the centres could confine themselves to dealing, at most, with minor ailments; at present this was not the case, and many children would remain untreated but for the work of the centres. The scope of the welfare centre was to fill any gap in the measures for preventing suffering to children, even if temporarily it ran up against other interests. An experienced medical chief was the first essential of a satisfactory staff, but Dr. Willoughby also placed great importance on highly trained health visitors for the homes. In Eastbourne the service of home helps had been found invaluable.

Dr. Mabel Brodie said there were three sides to the work—educational, medical, and social—and the first and last could be carried out by competent volunteers. Talks should be given, where possible, on health, sanitation, psychology, mothercraft, and housecraft, and in some cases such subjects as gardening and poultry-keeping might be included. It was desirable that where special home treatment was recommended, it should be demonstrated at the centre. Many mothers had no idea how to make a poultice or administer an enema. Often there was no district nurse to show them, and the health visitor had not time. People going into the newer type of house required instruction as to the respect due to the bath and sanitary arrangements, if these are to be kept in working order. Dr. Brodie would like the centres to be in the nature of mothers' clubs rather than out-patient departments, and to provide reading and rest rooms, and, where possible, a bath, which would be greatly appreciated by the mothers. The medical side should be preventive, but we had not reached that ideal at present, and minor dressings at least should be done at centres in places where there was no district nurse. Efficient medical officers were a necessity; whether male or female, it was essential that they should love babies, understand mothers, and be acquainted with the social affairs of the district.

Dr. E. Rowland Fothergill (representing the British Medical Association) said it was necessary to distinguish clearly between the centre and the clinic. The object of the centre should be educational and advisory, and medical treatment should not be given for any condition which, in the absence of the centre, would be recognised as calling for a doctor's attention. Mothers or children requiring medical treatment should be referred to the family doctor or, where there was no family doctor, to the clinic. The general practitioner was the pivot and anchor of the people's health, and every means of education and experience should be placed at his disposal.

Dr. Harold Scurfield said it sometimes seemed to be thought that babies and disease were invented for the benefit of the medical profession. The important thing was to get the necessary treatment and cure; it was useless to search out disease unless it was to be followed up by treatment. The panel system dealt with the worker, but there was at present no medical service at the disposal of the family.

The question of the advisability in urban areas of combining the functions of health visitor with those of other officers led to the expression of views on the whole more in favour of unification than against it.

Dr. W. E. Hope (M.O.H. Liverpool), in a paper read in his absence by Dr. S. G. Moore, gave some account of the evolution of public health work in Liverpool, and laid down the principle that certain preliminary training and experience were required for all health visitors, who, with this background, could readily assimilate special instruction to fit them for other branches of work.

Dr. F. E. Wynne thought the same tests in regard to specialisation ought to be applied as in medicine or surgery. In both cases the worker needed to have a sound knowledge of the whole field first, and then the particular section chosen should be sufficiently wide to occupy the whole energies of the specialist. It was almost impossible to avoid some overlapping while different branches of public health work were under separate Government departments.

In the final session on

Housing in Relation to Infant Welfare

Dr. Marion Cockerell gave a moving picture of the tenement house as she knew it in the borough of St. Pancras. It was common for a whole family to live in one room, and in most tenement houses there were no conveniences. Cooking had usually to be done on an open fire, and there was one sink, one w.c., and one dustbin for the whole house, all of which were only as clean as the least clean inhabitants. A house might be healthy as a whole, and yet people in certain rooms might be living in bad conditions. Those in the basement got no sunshine, and the babies showed poor resistance to disease of any kind. There were two possible remedies: first, to build new houses, self-contained and easy to keep clean; and secondly, to help some of the population to move into the country and live, not in mere suburbs, but in garden cities.

OPEN-AIR TREATMENT OF SURGICAL TUBERCULOSIS.

A VISIT TO ALTON.

THE vice-presidents, companions, and local honorary secretaries of the Queen Alexandra League were entertained by Sir William Treloar at Alton, Hants, on July 4th, on the occasion of the visit of Sir Clifford Allbutt. Sir William Treloar, before introducing Sir Clifford Allbutt, stated that the League was founded 17 years ago by Queen Alexandra for the purpose of collecting money for the Lord Mayor Treloar Cripples' Hospital and College, and during last year had raised over £9000.

Address by Sir Clifford Allbutt.

Sir Clifford Allbutt, after expressing his great pleasure at having this opportunity of seeing the remarkable work in progress at Alton, quoted Sir Anthony Bowlby as saying that the glory of Alton had abated surgery and that the old treatment of excision of joints had passed into oblivion. He gave a brief outline of the progress of medical knowledge in respect to tuberculosis, recalling the coddling treatment of this disease when even the keyholes were stuffed with cotton-wool in order to lessen the possibility of a draught reaching the patient. Tuberculosis, spread by infection, was a general disease, therefore local excision was not the best treatment. The value of open air, good food, and above all sunlight as means to increase the natural resistance was very potent. He stressed the importance of precise dosage and careful distribution in sunlight treatment in order that perils should be avoided and successes won. From Hippocrates onwards the law of reciprocal action, the ability of Nature to hit back, had been continually demonstrated. The intrinsic natural reaction of the individual was often strong enough to withstand infection. Open air increased the fortifications of the physiological reactions and replaced natural exercise in keeping the patient healthy. Alton was fortunate in having a pavilion with 50 beds at Hayling Island. Sir Clifford Allbutt paid a tribute to Rollier for his work in heliotherapy and occupation therapy; at Alton 14 teachers and four technical instructors were employed to keep the patients happily occupied. To the importance of early treatment and the value of following up cases after discharge he largely attributed the successful results, exclusive of accidents, in 95 per cent. of the cases sent to Alton. Sir Clifford Allbutt concluded by stating the two modern events which had given him the greatest pleasure—the remarriage of surgery with internal medicine after their long divorce, and the formation of an institute of comparative medicine at Cambridge.

The Work at Alton.

The work at Alton is too well known to need detailed description. Amongst its many interesting features may be mentioned the observation ward where each new patient admitted is kept for a period of at least a fortnight in quarantine. Each child occupies a separate cubicle and during his stay the case is worked up, his educational standard ascertained, X rays taken, and necessary splints manufactured. After that the patient is warded—or rather gradually acclimatised to open air and sunlight—not according to age or medical classification, but according to his standard of intelligence and school class. Non-inflammable perforated celluloid plasters and various splints and methods of extensions invented at Alton are in use with remarkable results. The difference in degree of pigmentation was considerable, every child having an individual reaction to sunlight. The red-haired, much freckled white-skinned type are unable to tolerate exposure and have consequently a less hopeful prognosis. The beds in the "Hampshire" ward are heated electrically, Alton being the first hospital to adopt this method. In sharp contrast to cases of surgical tuberculosis as seen in a general hospital or out-patient department is the total absence of muscular wasting. This is attributed to the action of open air on the skin—a loin cloth and sun hat is generally the only covering. The effect of fresh air on naked skin has been proved by Dr. Leonard Hill, Dr. Argyll Campbell, and Sir Henry Gauvain to increase greatly the metabolism of the body. It is stated that the pigmented patients at Alton, even though suffering from surgical tuberculosis, have their working capacity increased on an average by 37 per cent. beyond that of normal healthy children.

Alton is a striking example of what a hospital, situated in ideal country surroundings, supplying its own vegetables, fruit, pigs, and eggs can do for its patients.

MEDICINE AND THE LAW.

LIABILITY FOR IMPURE WATER-SUPPLY.

AFTER litigation extending over two years the High Court of California, U.S.A., has recently awarded substantial damages, to be paid by the city authorities, to 19 persons who contracted typhoid fever at Pittsburgh, in consequence of a breakdown in the apparatus for purifying the city's water-supply. This is drawn from the Sacramento river, the water of which is recognised as unfit for drinking until properly treated, and at a date preceding the outbreak of typhoid, from which the plaintiffs suffered, the chlorinating plant was for a time inoperative owing to the fixtures upon a drum containing chlorine gas not permitting of its attachment to the pumping system until the necessary alteration of the fittings had been made. The court has held that an obligation lies upon the city authorities who distribute the water to use all reasonable precaution to render it fit and wholesome. Presumably, in terms familiar in our courts, the judgment was to the effect that there was negligence in not securing a supply of chlorine gas in a receptacle suitable for use in the machinery installed for the purpose, and in allowing water to be supplied in a condition known to be unsafe, and without warning to the public. Subject to any special provision not likely to be inserted in any water company's Act, there can be no reason why such an action should not lie in this country in similar circumstances.

AUTHORITY TO ENGAGE AN AMBULANCE.

At Romford County Court recently his honour Judge Crawford tried an unusual action, in which the Romford Urban Council sued a Mr. Thwaites for payment for the use of the town ambulance to convey him to a London hospital. Mr. Thwaites denied liability and said that he could have travelled by omnibus or similar conveyance, and that the ambulance had been ordered by his medical attendant, Dr. V. Levy, without his authority. Accordingly the Council had joined Dr. Levy as a defendant and he was represented at the trial by Mr. H. F. Dickens, briefed by the solicitor to the Medical Defence Union. As to the main facts there was no dispute. Dr. Levy had attended Mr. Thwaites, who was suffering from severe abdominal pains, and on receiving a second summons decided that the case was one of urgency, and accordingly, on his way to his patient's house, asked for an ambulance to be sent at once to take him to a hospital. He told the court that he would have been running a great risk if he had allowed any delay to occur. On Mr. Thwaites saying that he could have travelled in an omnibus or tram-car Judge Crawford asked, "Don't you think that the doctor was the best judge of that?" In giving his decision, Judge Crawford compared the case to that of the captain of a ship who when out of reach of his owners had to come to a decision and take responsibility on their behalf. A doctor in a similar case of great urgency became, in his opinion, an "agent by necessity" and was fully justified in taking whatever steps he might think necessary in his patient's interest. Ambulances were modern inventions to secure the safe conveyance of patients, and though he knew of no parallel case, the principles of the common law would apply. If the man had died he had no doubt that his relatives would have blamed the doctor if he had not taken proper precautions. Such cases must often arise, but the question of payment had not before been contested by the patient. The defence was one of the most discreditable he had ever known. He agreed that the matter was of great interest to the general public and to the medical profession, and in giving judgment with costs against Mr. Thwaites for the amount claimed by the Urban Council, he ordered him to pay Dr. Levy's costs and certified for the costs of counsel who appeared for him. Dr. Levy is to be congratulated and also the Medical Defence Union, who no doubt will record the case as a valuable precedent for the application of the law of "agent by necessity" in medical matters.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of G.P.I. by Inoculation of Malaria.

INTEREST has been aroused by a further communication made to the Vienna Neurological Society by Prof. Wagner-Jauregg, dealing with the results of treating 300 severe cases of general paralysis of the insane by infecting them with tertian malaria. In 1890 Prof. Wagner-Jauregg produced a "curative" febrile condition in such patients by inoculating old tuberculin (Koch). Cases were taken without selection, and it was apparent that the febrile cases had a better expectation of life. He then combined the tuberculin treatment first with mercurial treatment, later with salvarsan, and the results were comparatively satisfactory. In 1909 a report on these results was given at the International Medical Congress in Budapest; some of the patients referred to in that report are still alive and actively working. Of the total number of 86 cases, 23, or 27 per cent., could be classified as having regained full fitness for work; 50 per cent. had lasting remissions. Early cases had better chances of recovery than inveterate cases. Improved results were obtained by the use of polyvalent typhoid vaccine (Besredka), which produced more lasting febrile attacks, and remissions after its use were decidedly longer. Wagner-Jauregg noted that an intercurrent infectious disease, occurring in such patients when they were under the influence of tuberculin or typhus vaccine, produced a definite cure. In 1917 he resolved to infect such patients with the plasmodium of tertian malaria. Nine patients were taken as a first experimental group; of these, 6 are at present (i.e., six years later) perfectly well and fit for work; three had long periods of remission. Having kept this first group under observation for two years, Wagner-Jauregg then conducted large-scale experiments, and his clinic now contains records of over 300 cases treated in this way. The method seems to be the most successful of all known and is applied as follows: Tertian plasmodia obtained in vivo are injected intravenously; an incubation period of 8–14 days follows, and then comes the typical attack. The patient is allowed to undergo 8–10 attacks of fever, and quinine sulphate is then given in the orthodox way; this treatment is followed up by neo-salvarsan injections, which have lately been combined with cerebro-spinal drainage. In 1920 a series of 25 cases, with 9 complete cures, was demonstrated at the meeting of German natural scientists at Nauheim. In 1922 the number had gone up to 294 cases, with 112 complete cures, and 88 long remissions (reported at Leipzig). The improvement is noted some time after the fever treatment; it continues to increase gradually until a full remission is observed. It was found possible to transform an incomplete remission into a complete one by repeating the whole series of treatment. Reports of observations of the same nature have come from numerous other places—e.g., Graz, Heidelberg, Göttingen, and Munich. Another important observation has been made by Prof. Kyrle (assistant of Prof. Zinger) on the treatment of secondary manifestations of syphilis by injection of tertian malaria with very satisfactory results. The experiments are not yet concluded, the time being still too short for definite conclusions to be drawn, but there seems reason to envisage the possibility of radical cure of syphilitic infections by combined malaria-salvarsan treatment.

Closing of All Schools for Dental Mechanics.

By an order of the Board of Health the existing schools for technical dentistry open for non-medical pupils will be permanently closed at the end of the summer term. This is the final result of the "Dental Mechanics Act," introduced in July, 1920, by which all dental work in the mouths of patients is handed over to medical men only. The dental mechanic will in future only serve as an apprentice or qualified workman in the workshop of a dental surgeon; instruction in technical dentistry will be obtainable exclusively in dental clinics, open only to doctors of medicine. The non-medical dentists at present practising will retain their position, which will even be a little extended in so far as they are permitted to extract teeth and to fill and treat diseased roots. The apparatus of the once famous Dental Mechanics School of Vienna will be handed over to the Vienna Dental Clinic. The Act also terminates dental practice under titles such as "doctor of mechanical dentistry" and "licentiate of dentistry" obtained abroad.

Vaccination Against Measles.

At a recent meeting of the Vienna Medical Society a report from the "Mautner Markhof Children's Hospital," presented by Prof. Leiner, recorded results obtained by the method of Dr. Degkwitz, of Munich, of vaccination against measles. This disease has a tendency to become very dangerous every third year, especially with children below the age of one year. In the 1919–20 epidemic older children were also frequently fatally affected, and in 1922–23 the winter season was again accompanied by severe mortality, particularly in several children's hospitals. Dr. Degkwitz took 60–80 g. of blood from children in the convalescent stage of measles and prepared from it a serum, of which 3 c.cm. were injected intramuscularly into children in direct contact with measles patients. The earlier this prophylactic immunisation took place the better were the results seen. If set up on the second to the fifth day after contact it was still efficacious, being less protective on the sixth to the eighth day, although even then the course of the disease was mild and transient. The control experiments conducted in Vienna have fully confirmed the claims made at Munich, and the serum will be manufactured in large quantities for use in private practice.

Prophylactic Inoculation of Dogs Against Rabies.

In my letter of June 13th[1] a paragraph referred to anti-rabies measures in Austria. The following information may now be added. Prophylactic inoculation of dogs against rabies has been undertaken in Vienna; of 90 animals inoculated according to Pasteur's method, and then subjected to an "experimental" bite by a diseased animal, not one developed rabies. There is a growing desire among the public for general anti-rabies inoculation of the dog population. Four injections of vaccine on four consecutive days would, it is estimated, cost 30,000 kroner (2*s.*).

Autumn Post-Graduate Courses.

The Medical Faculty of Vienna will hold a post-graduate course for Austrian and foreign practitioners from Sept. 17th–29th. Lectures will be as follows:—Sept. 17th: Errors in Diagnosis of Diseases of the Eye; Diagnosis and Treatment of Trachoma; Cataract; Strabismus.—Sept. 18th: Vertigo; Pain in the Study of Otology; Important Surgical Indications in Diseases of the Ear; Deafness; Tonsillectomy.—Sept. 19th: Traumatic Neuroses; Diagnosis of Early Progressive Paralysis; Treatment of Progressive Paralysis; Psycho-analysis.—Sept. 20th: Tuberculosis in Children; Stridor in Children; Parasitic Worms in Children; Differential Diagnosis of the Exanthemata.—Sept. 21: Deficiency Diseases; Albuminuria in Children; Syphilis Neonatorum; Advice to Mothers.—Sept. 22nd: Prevention of Goitre; Modern Cardiac and Vascular Remedies; Diseases of the Liver; Disorders of Metabolism.—Sept. 24th: Diseases of Internal Secretion; Tuberculosis of the Lungs; Heart Disease; Intestinal Diseases.—Sept. 25th: Distinction Between Obstetric Indications in the Clinic and in Private Practice; the Possibility of Restoration of Function by Operation in Gynæcology; "Hormone-therapy" in Gynæcology and Obstetrics; Causes of Danger to the Child During Pregnancy and Birth; the Relation of the Special Sense-Organs with the Genital Organs in the Female.—Sept. 26th: Indications for and Success of Radiotherapy in Gynæcology; New Methods of Examination in Gynæcology and Obstetrics; Metritis, Endometritis, and Uterine Disorders; Gonorrhœa of the Uterus; Urology for the Practitioner; Tubal Pregnancy; Delayed After-birth.—Sept. 27th: Modern Treatment of Syphilis; Treatment of Eczema; Radiotherapy; Sexual Offences.—Sept. 28th: Indications for Urgent Operation; Surgical Indications in Diseases of the Biliary Tract; Surgery of Accidents; Surgery of the Mammary Glands.—Sept. 29th: Ætiology and Diagnosis of Intestinal Cancer; Treatment of Fractures by Simple Means. A Clinical Course will follow from Oct. 1st to 6th. Those intending to take the post-graduate course should send name, address, and title to Dr. Kronfeld, Porzellangasse 22, Vienna. Fee for Austrians and Germans, 25,000 kroner; for Bulgarians, Jugo-Slavs, Poles, Russians, Czecho-Slovaks, and Hungarians, 100,000 kroner; for other foreigners, 200,000 kroner. Other courses, beginning on July 2nd, August 1st, or Sept. 3rd, will be held in the following subjects: (1) Anatomy, Medical Chemistry, Physiology, History of Medicine; (2) Forensic Medicine; (3) Internal Medicine; (4) Diseases of Children; (5) Neurology and Psychiatry; (6) Surgery and Orthopædics; (7) Rhino-laryngology; (8) Ophthalmology; (9) Otology; (10) Gynæcology and Obstetrics; (11) Skin and Venereal Diseases; (12) Urology; (13) Radiology.

---

[1] THE LANCET, June 23rd, p. 1284.

June 29th.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Death of Dr. Hermann Biggs.

Dr. Biggs became ill on June 2nd in his holiday camp at Little Moose in the Adirondacks. Returning to his home in New York, the State health commissioner never rallied and died on June 28th. The diagnosis of broncho-pneumonia was confirmed by autopsy, for Dr. Biggs had particularly requested his friend, Prof. Ewing, of Cornell University to perform this service. Hermann Michael Biggs was born in Trumansburg, N.Y., on Sept. 29th, 1859. After graduating A.B. Cornell in 1882 and M.D. Bellevue Hospital Medical College in 1883, he studied in Berlin and Griefswald. In 1895 he directed the production of the first diphtheria antitoxin in this country. He has been director of the Rockefeller Institute of Medical Research since its organisation in 1901. In 1900 he became general medical officer of the New York city health department, with which he had then been connected for 12 years. He was instrumental in establishing the New York City bacteriological laboratory, the first municipal bacteriological laboratory in the world, and quickly made a reputation as one of America's leading bacteriologists. He remained with the city health department until 1914. The mortality statistics in New York City underwent a rather startling change during his administration, the general death-rate falling from 18·6 per 1000 in 1902 to 13·78 in 1913. The corresponding rates for the State of New York were 14·4 per 1000 and 15·4 per 1000 respectively. During this period he was largely responsible for formulating and directing the campaign against tuberculosis in New York that was so warmly commended by Koch in 1908, and that has been so successful. In January, 1914, Dr. Biggs was appointed Commissioner of Health to New York State—a post which he had three times previously declined. In this position, as in his former post with the city, Dr. Biggs was not only responsible for a great body of wise legislation, but he showed a wide constructive imagination in his work of popular education. During the war he was a member of the Relief Commission of the Rockefeller Foundation, he attended the international conference at Cannes, which gave rise to the League of Red Cross Societies, and subsequently was, for a short time, medical director of the League. Both the conference and the League secretariat profited greatly from his unusual executive ability.

His life was filled with fruitful and unselfish endeavour—we have listed above only a part of the distinguished services which he gave to his country and to the world. There is no doubt he might have made a fortune by the private practice of his profession. He preferred to spend himself in a cause which even in America is not well-paid, but which, thanks to the fine example of such pioneers as he, is yearly absorbing more and more of the finest minds in medicine.

American Medical Association Convention.

Signs are not wanting that the whole body of the profession is looking more and more towards methods of early diagnosis and prophylactic treatment. Thus the opening address to the A.M.A. Convention, held this year at San Francisco, brought strongly to the attention of delegates that the objects of the Association are to promote not only "the science and art of medicine" but also "the betterment of public health." Dr. R. L. Wilbur, of Stanford University, the president-elect, reminds us that we "can make our particular civilisation secure only by developing and controlling our food-supply and housing, holding aloof our enemies, particularly the microscopic ones, keeping up proper physical standards of individual and group health, and having ideals of service and religion that make life coöperative and wholesome." But while modern civilisation calls for public health legislation and the health supervision of industry, the individuality of the physician must be conserved. "The voluntary association of two men, one giving and one seeking relief, is at the heart of the art of medicine."

The chairman of the Council on Health and Public Instruction announced that a subscription list of 12,800 has already been secured for *Hygeia*, and judging by the high standard which this journal is maintaining—the July number contains an admirable article by Dr. Victor C. Vaughan on Small-pox Before and After Jenner—this circulation must certainly increase.

June 29th.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. J. G. Gill retires on ret. pay.

Maj. E. V. Aylen to be Lt.-Col. to complete estabt.

TERRITORIAL ARMY.

General Hospitals: Maj. A. G. Gibson relinquishes his commn. and retains the rank of Maj.

Capt. J. W. Stretton relinquishes his commn. and retains the rank of Capt.

General List: Capt. T. D. Webster resigns his commn. and retains the rank of Capt.

J. D. M. Cardell to be Lt.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon Lt.-Col. (Bt. Col.) A. B. Gemmel (retd.), Majs. A. B. Murray and H. M. Fort, Capt. E. P. Minett (ret.), and Capt. and Qr.-Mr. N. Greenwood.

SMALL-POX IN GLOUCESTER.

STATEMENT BY THE MINISTRY OF HEALTH.

IN view of the public attention attracted by the outbreak of small-pox at Gloucester, the Ministry of Health has issued a statement to the following effect.

Origin of the Outbreak.

The outbreak at Gloucester was not dealt with as soon as it might have been, because of the refusal of the local medical officer of health to admit the presence of small-pox on a large scale in the city. There were, however, admitted cases of small-pox as early as April, and he was advised of the danger by the Ministry of Health early in May on cases of small-pox occurring at places as distant from Gloucester as Liverpool and Abertillery, the source of infection in which was traced to Gloucester. At the end of May, a medical officer of the Ministry of Health, present in Gloucester on a public inquiry, visited various suspected cases reported to him by medical practitioners which he diagnosed as small-pox. The medical officer of health did not agree and Dr. A. F. Cameron, medical superintendent of the M.A.B. Small-pox Hospital at Dartford, was then invited to the city and agreed with the diagnosis of the medical officer of the Ministry of Health. A subsequent house-to-house visitation by officers of the Ministry of Health established the existence of epidemic conditions beyond dispute. The local authority dealt with the situation by entrusting charge of it to Dr. W. H. Davison, senior assistant medical officer of health, Birmingham. A special hospital was set up, special vaccination stations were established, and all contacts were traced as far as possible in view of the time which had been allowed to elapse. While fresh cases are still occurring, the situation is fairly in hand, though there is urgent need of vaccination of the population.

The Present Distribution of Cases.

The table (the figures in which are subject to revision) shows the number of cases of small-pox reported during each of the four weeks ended on June 9th to June 30th in the various sanitary districts of the country.

District.	Week ended June—			
	9th.	16th.	23rd.	30th.

R.D., Rural District. U.D., Urban District.
C.B., County Borough.

It will be seen that the total number of notifications for these four weeks is 408—as compared with 151 in January, 154 in February, 214 in March, 141 in April, and 112 in May.

Help in Diagnosis.

The particulars given as to the outbreak at Gloucester indicate the dangers of incorrect diagnosis. It is the duty of the general practitioner to notify small-pox to the medical officer of health, and if he is in doubt as to diagnosis he consults that officer. If in his turn the latter has any doubt, he applies to the Ministry of Health and the medical staff of the Ministry at once assists him by advice on the spot as to diagnosis and as to the action which should be taken to stamp out infection locally and prevent its spreading. In view of the number of calls now being made on the Ministry and the limited staff available, arrangements have been made by which medical officers of health, especially expert in small-pox, are ready to give immediate help as required in each of 12 districts into which the country has been divided for this purpose.

Vaccination in Relation to Further Spread.

The statistics show that the incidence of small-pox at present is very widely spread over the country. The number of notifications in the first six months of the present year is largely in excess of the notifications for the whole of last year, and is out of all comparison with the experience recorded since the last epidemic period, 1902–04. In view of the extent to which vaccination of infants has ceased (the percentage of vaccinations for the whole country in 1921 being 38·3 per cent. of births, as compared with 70·9 per cent. in 1907), and in view of the rarity of revaccination among the adult civil population, the Ministry of Health regard the situation with concern and hold the view that there is distinct risk of an outbreak of a serious character. The only practical remedy, now that the infection has been introduced, is increased recourse to vaccination, and the Ministry of Health would urge that this remedy should be made use of as widely as possible. Vaccination can be obtained free of cost by reference to the public vaccinator in the area, who uses lymph of approved quality supplied by the Government Lymph Establishment at Hendon. The reserve of tubes at Hendon is well over a million at present, and can be expanded as required.

MANCHESTER: CARE OF THE BLIND IN THEIR HOMES.—At the annual meeting of the Manchester and Salford Blind Aid Society held at Manchester on July 5th, Mr. E. D. Macgregor, of the Ministry of Health, and other speakers paid a tribute to the society's good work in the care of the blind in their homes. Founded in 1900, the society now accommodates 20 blind men and 20 blind women at the Memorial Home of Rest in Southport, and also gives a holiday there to about 400 blind persons each year; at another home 30 homeless blind women are provided for, and at a third home are 30 more blind of both sexes. According to the latest returns some 35,000 persons in England and Wales are blind within the definition of the Ministry of Health—i.e., so blind as to be unable to perform any work for which eyesight is essential, but it is possible that the actual number is nearer 45,000. Of the 35,000 more than 55 per cent. are over 50 years of age, and approximately 50 per cent. are untrainable and unemployable, blindness in a considerable number of cases being accompanied by other physical or mental defects arising generally from the same cause as produced the blindness. Venereal disease is the largest single contributory cause of blindness, and accounts for 25 per cent. of the cases. There is some reason for believing that the incidence of blindness is declining and it is clear that ophthalmia neonatorum is decreasing. Mr. Macgregor, in outlining the organisation he conceived to be necessary for the blind in a city like Manchester, said that no city in the country was better placed for securing such an organisation than Manchester. The Corporation of Manchester, said Mr. Macgregor, had not so far as he knew yet spent one penny as an authority under the Blind Persons Act, and it was three years since that Act was passed, but there were signs of Manchester moving in the right direction in this work.

Public Health Services.

THE HISTORY OF PUBLIC HEALTH EFFORT IN MANCHESTER.

AN illuminating and suggestive chronicle of the activities of Dr. James Niven. the late medical officer of health, while in the service of the Manchester Public Health Committee. since 1894, is given in a recently published manual,[1] which includes also an account of the work achieved by the committee in so far as Dr. Niven himself had any personal share in it. The chronicle is that of an unfinished task. Dr. Niven would like to see certain branches of public health come under the medical officer of health as coördinating and directing head. notably first the work of the cleansing department, which needs to be directed in subordination to the sanitary requirements of the city, as interpreted by the city's adviser in public health matters. This is equally true with regard to the department which deals with unwholesome foods. The control of infectious disease and the sanitation of schools should similarly, according to Dr. Niven, be placed under control of the medical officer of health, as they originally were, in the same sense as the control of tuberculosis is his responsibility. He believes that by far the most important influence which has governed the improvement of the public health in Manchester, apart from economic conditions, has been the removal of organic filth, whether within or without the habitations of the people. Probably the next in importance has been the control of infectious disease. No less weighty in their effects have been the economic advance of the town and the consequent diminution of poverty, though it is not easy here to trace cause and effect. Much of the bad housing in Manchester is inseparable from the removal of filth. Improvements of a positive character, such as the institution of parks, the physical care and training of children. the provision of public baths and washhouses, have also contributed much to the health of the city. The provision of an abundant and pure water-supply and of a varied food-supply of good quality has also been a factor in health, and the part played by education has not been small.

The annual health reports for the city of Manchester date back to 1868, when Dr. John Leigh was appointed the first medical officer of health, and the city had an estimated population of 345.295. From 1832 until this period the annual death-rate remained at about 32 per 1000. In Dr. Leigh's report for 1869, he records that so numerous were the inhabited cellars in Manchester a few years ago that it might well have been considered a city of cave-dwellers. Under the heading of infectious diseases many practical suggestions are given. Noteworthy are the remarks on "overlooked cases" in scarlet fever, one of the most potent causes of the spread of this disease. Measles is regarded as peculiarly a disease of poverty—that is, in so far as the death-rate is concerned. Tuberculosis, on the other hand, is described as a poverty-making disease, and it is suggested that a high percentage of the existing poverty is attributable to this cause. It may come as a surprise to many that the staff employed in 1921 in the public health department, under the medical officer of health reached a total of 861; included in this total are 215 at Monsall Fever Hospital and 186 engaged in tuberculosis work; health visitors account for 62. maternity and child welfare centres 40. and in the sanitary department 231 persons were employed.

In a final review of the work achieved during his tenure of office Dr. Niven expresses gratitude for the constant support given him by the medical profession, without which no public health service can be successful. On this cordial note does Dr. Niven bring to an end a survey of his stewardship as medical officer of health of the city of Manchester, a survey that may be read with profit by every medical officer of health in Great Britain and beyond.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are the principal health statistics of a group of boroughs of varying size for the year 1922:—

Name of borough.	Estimated population (mid-year).	Birth-rate.	Death-rates per 1000 of population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Halifax C.B. ..	100,500	15·9	14·9	1·1	—	—	112	75	6·2
Warrington C.B.	79,150	22·6	12·1	1·7	0·9	3·2	70	175	2·8
West Bromwich C.B.	76,260	24·1	14·1	0·9	0·8	4·6	86	141	5·5
Guildford B. ..	24,950	17·0	11·6	0·8*	1·4	2·7	40	111	0·0
Leamington B...	28,740	18·0	13·9	1·1	1·3	2·3	58	55	11·6
Shrewsbury B. .	31,240	19·5	13·3	1·5	1·6	3·3	43	138	3·3
Watford B. ..	46,610	19·0	9·6	1·0	0·9	2·3	55	100	3·3
Yeovil B.	15,280	17·6	10·4	1·0	1·6	2·0	53	333	3·7

C.B. = County borough. B. = Borough.
* Pulmonary tuberculosis only.

Halifax.

Dr. Cyril Banks. in reviewing the records of Halifax, points out that the general death-rate and infantile mortality rates are not good, and that the record of deaths of mothers in childbirth for 1920 and 1921 is a sad one. Although infantile mortality has shown a great drop in the last 30 years, there is no decline in neo-natal deaths. and the ante-natal clinic is not yet a success. Dr. Banks unhesitatingly condemns the Goux pail conservancy system, which is still the system in most general use for dealing with human excreta. An effort is being made to do away with tips and to adopt an up-to-date method for dealing with household refuse. An effort is also being made to deal with smoke abatement more effectively, and lectures have been arranged for stokers. A movement has been made towards the avoidance of overlapping (coördination) by employing the health visitors to visit tuberculosis cases. Apparently there is an idea prevalent in Halifax that an untrained woman may conduct the delivery of a midwifery case where a doctor has been engaged. Amongst other needs mentioned by Dr. Banks are properly constructed scarlet-fever wards, and improvements to the public slaughter-house.

Warrington.

Dr. G. W. N. Joseph mentions that, in these days, when economy is so necessary, there is room for a great advance without much expenditure by educating the people in the principles governing health. Housing is still the urgent question; 37 municipal houses were completed during the year, and 36 more were nearly completed. The points considered in allocating municipal houses are overcrowding, expectant mothers. occupation of bedrooms by adults of opposite sexes. husbands forced to live apart from their wives, and tuberculosis. There are still 673 overcrowded applicants on the waiting list. There are also 602 applicants not overcrowded. and 134 who live outside but mostly work in the borough. There is much profiteering among those who let lodgings, so that the lodgers are "taken in" in a double sense. "Unfit" houses cannot be closed.

---

[1] Observations on the History of Public Health Effort in Manchester. By James Niven. M.A., M.B., LL.D. Published by the City of Manchester. John Heywood, Ltd. 1923. Pp. 230.

and perineum in all operative cases are painted with iodine before interference. On the district, shaving is not always done on account of the prejudice against it, but it is considered advisable and the keen midwives adopt the practice. At present we provide for each district case, two sterilised pads, and for stitch cases, gauze dressings. If an instrumental case is near enough to the hospital, we send out towels, overalls, pads, and the like. All our midwives are taught to make vaginal examinations in gloves and to deliver in gloves.

With regard to antenatal work, I strongly support Lady Barrett. I have had dental treatment carried out in numerous cases, both at Woolwich and at the Welfare Centre of the Women's League of Service at Hammersmith. Gas is always given for extractions, and I have never known any ill-result. We use every effort to train the midwife pupils to rely on abdominal examination and to avoid vaginal examinations in all cases where the size and position of the head suggest the possibility of a difficult delivery.

The importance of an anæsthetic in the second stage cannot be too strongly urged in order to get full control as the child is born, and to avoid tears and their sequelæ.—I am, Sir, yours faithfully,

MARY A. BLAIR, M.D., B.S. Lond.

Belgrave-road, S.W., July 6th, 1923.

PROTEIN IDIOSYNCRASY AND ASTHMA.

To the Editor of THE LANCET.

SIR,—We have recently had under our care two cases of asthma which we think are of special interest. The first is a sufferer with ten years' history of frequent incapacitation, and the second a man who had his first attack on occupying the room vacated by the first. The suggestion of a connexion between these two events was increased by the discovery that the second man, L., had a positive cutaneous reaction to the protein, for which the first man, K., had received the antigen as a therapeutic measure. As briefly as possible we wish to record the salient features of both cases and the steps in our investigation into their possible relationship.

K. is a man of 29, who for nine years had attacks of asthma at intervals of about a month, with the exception of a period in the summer of 1920, when he enjoyed five months practically without symptoms. The attacks occurred during the night and from four to six nights in succession. They were frequently associated with taking cold; they had appeared to follow the taking of certain fruits, and a psychical element in causation had been noted on an occasion when asthma immediately followed a gasp of admiration on seeing a challenge cup won by comrades. Relief invariably followed the administration of adrenalin, and two minutes after the injection of V $\frac{1}{1000}$ adrenalin solution, the vital capacity had been found to have increased from 300 c.cm. to 1750 c.cm. The bronchial catarrh associated with asthma was always a marked feature, and it usually persisted for several days after amelioration of the bronchial spasm. Severe attacks were associated with a febrile reaction and occasionally herpes of the lips.

In December, 1922, K.'s statement that he thought attacks were induced by taking apples led to an investigation of his protein susceptibility by means of cutaneous reaction. There was no reaction to group proteins for fruits, but there was a positive reaction to organism A. Respiratory tract (streptococcus, staphylococcus, pneumococcus and influenza bacillus). As symptoms and physical signs of simple respiratory infection had accompanied the asthma, K. was then given a series of doses of antigen prepared from this protein, commencing with a dose of five units on Jan. 31st, 1923, and ending with a dose of 1000 units on March 7th. There was a mild attack of asthma during this course, but since its completion there has been no return of bronchial spasm. K. had hitherto shared a room with a friend, A., but while the inoculations were in progress he was accommodated in a ward. On May 7th he returned to his room rejoicing in his newly acquired resistance, only to "catch a cold" and return to hospital on the 18th with a temperature of 101·4° F., respirations 36, and pulse 128. Bronchial spasm was this time not absent, but barely recognisable, while the bronchial catarrh element was severe. Moist sounds appeared in the lower lobes of both lungs, there was copious frothy sputum, and the attack ended as had done former attacks of asthma, normal health being regained on May 25th.

In the meantime, K.'s friend A. changed his quarters, and on May 30th K.'s old room was occupied by two men, L. and G. On June 5th L. had the first attack of asthma of his life. It was mild, but attacks on the succeeding nights were worse, and on the morning of May 9th he was unable to go to work and sought medical aid. He was admitted to hospital with a typical and severe attack of asthma, which quickly improved, and from which he had completely recovered on the 13th. After a week's interval, during which time he had normal health, cutaneous reactions were carried out and L. was found to have a slightly positive reaction to organism A.

Our next step was to investigate the skin reactions of the room-mates of these two men—i.e., A. and G.—and in both cases negative results were obtained. During June 18th, 19th, and 20th, K. and L. were accommodated together in a small side ward. On the evening of the 20th both men were discharged from hospital, and L. returned to the now suspected room, K. entering an adjoining room. On the night of June 22nd–23rd L. had an attack of asthma. This was repeated on the 24th, and on the 25th he was again removed from the room. After June 25th K. and L. have been in close association without apparent ill-effect in either case.

We regret that an urgent demand for side-ward accommodation induced us to terminate the isolation of K. and L. after three days together. L.'s first attack occurred six days after entering K.'s room, and his second six days after meeting K. and three days after re-entering K.'s room. We are, however, inclined to the opinion that his attacks occur rather in the suspected room than in the presence of K. Both patients have had symptoms and signs which, in the past, have led to a diagnosis of pulmonary tuberculosis, but in neither case has the tubercle bacillus been found in the sputum. K. has had attacks in many places, but has always associated certain localities with severe attacks. As described above, a psychical element has been recognised in his case, but it must be noted in this connexion that, as a soldier, he was never prevented from entering or leaving the line by asthma.

The following questions now present themselves: Is K. a carrier of micro-organisms producing a protein to which both he and L. are susceptible? As the room is specially constructed and maintained for the reception of ex-sanatorium patients, it would seem hardly likely that infection could take place after a lapse of 12 days, during which time the room was unoccupied. Are both K. and L. in constant presence of similar organisms but only liable to bronchial spasm under certain undiscovered conditions existing in this room? These are questions which we hope to investigate, but we consider that the unusual and definite nature of the phenomena with which we have come in contact merit their early publication.

We wish to record our indebtedness to Dr. P. C. Varrier-Jones for permission to publish the foregoing notes. We are, Sir, yours faithfully,

L. B. STOTT,
B. R. A. MORTON.

Papworth, Cambridgeshire, July 5th, 1923.

THE LYMPHOCYTOSIS OF INFECTION.

To the Editor of THE LANCET.

SIR,—I suggest that Dr. H. L. Tidy and Dr. E. C. Daniel have, in your current issue, committed themselves to statements which are of a somewhat too comprehensive nature. They record their opinion that "glandular fever and the condition described as infective mononucleosis are identical," and further, that the conception of infective lymphocytosis is based on articles which "reveal no evidence for the statement . . . . . that sepsis is a rare but occasional cause of absolute lymphocytosis." I readily admit that some of the cases brought forward in support of this view were cases of glandular fever, which Dr. Tidy has done so much to establish in its true position as a clinical entity, and that others were cases of leukæmia—e.g., the case of Sanders. But a residuum of cases fails to fit in under either heading, and some of these cases are contained in those articles which are so unceremoniously dismissed.

Cabot has the credit of first calling attention to a condition which he described under the heading, "The Lymphocytosis of Infection." His first case was that of a septic infection of the finger followed by lymphangitis and enlargement of axillary glands. The blood changes are not given in detail, but a statement from Cabot that there was "throughout a well-marked, absolute and relative lymphocytosis" has more value than mere figures. Fever continued for "several weeks," but the patient recovered and was in good health 15 years later. This is not the picture of leukæmia, nor is it that of glandular fever. Yet Dr. Tidy says that "glandular fever and the condition described as infective mononucleosis are identical." There is a further aspect of the question which may be considered—namely, that there exists an infective myelocytosis—e.g., that recorded by Simon[1]—which would appear to bear much the same relation to myelæmia as infective lymphocytosis does to lymphæmia. There are good reasons for supposing that a hyperplasia of the hæmopoietic tissues, comparable to that of leukæmia in all but degree, may complicate various septic conditions, and is further of such frequent occurrence as to be typical in mumps (in early years of life) and in glandular fever.

But it may be doubted whether the recorded cases warrant any more sweeping assertion than this.

I am, Sir, yours faithfully,

Sevenoaks, Kent, July 6th, 1923. GORDON WARD.

TUBERCLE ANTIGENS.

To the Editor of THE LANCET.

SIR,—In your issue of June 30th you draw attention editorially to recent work of Dr. A. R. Jentzer and his fellow-workers regarding the attack on the acid-fast coat of the tubercle bacillus *in vivo*. These workers inject or use a proprietary preparation or compound of fats, lipoids, and waxes. Prof. G. Dreyer, as is well known, removes the fatty and waxy capsule of the tubercle bacillus *in vitro* by formalin-acetone. In both the methods centre on the waxy and fatty protective coat. According to Dreyer, the removal of the acid-fast substances releases the protein antigen. This is thus more readily soluble in trypsin, and after injection is more effective in the production of various antibodies. On the other hand, according to Jentzer and his colleagues, it is claimed that their compound of fatty and waxy substances "stimulate the tissues to produce ferments which not only saponify the fatty and waxy substances introduced by parenteral injection, but also the fatty, lipoid, and waxy constituents of the tubercle bacillus." This method of attacking tuberculosis is described as novel, and in a sense to some extent as anticipating the work of Prof. Dreyer, but the exact composition and mode of manufacture of the compound of the fats, lipoids, and waxy substances used by Jentzer and his colleagues are not published. May I point out that the employment of the fats and lipoids and the theory therefrom constructed is not novel? For many years various aspects of the fat-splitting action of the pancreas has occupied my attention. The results of my work, carried out in the physiological and bacteriological laboratories, King's College, have been published in THE LANCET and elsewhere.[2] The main outcome of this work has been to show that a natural and increased production of lipase in the blood and tissues is an important factor in the protective mechanism of the body. This is particularly the case in malignant disease, although I have pointed out that this lipolytic defensive response is not specific to cancer but is common to tuberculosis and other bacterial invasions. This I have expressed in identically the same terms as employed by Jentzer and his colleagues. Lipase, moreover, lends itself naturally to attacking the fatty and lipoid coat of the tubercle bacillus *in vitro*. As long known, lecithin is split by lipase and accelerates also the activity of that enzyme *in vitro* and *in vivo*. In my experiments it was found that fatty acids are liberated by lipase from killed tubercle bacilli *in vitro*. In this way saponified extracts were prepared and indicated for therapeutic use. Preparations were made also by extracting tuberculous material with the usual fat and lipoid solvents, alcohol, ether, and chloroform successively, in a Soxhlet's apparatus in the usual way, and saponifying the extracted material or emulsifying. This method in the main differs essentially from that of Jentzer and his colleagues in that the *products* of the fats and lipoids of tubercle bacilli are used, together with protein and phosphate derivatives or constituents of the bacillus. The soaps themselves—e.g., sodium oleate, organic and inorganic phosphates, and proteins—have marked power in stimulating tissue lipolytic activity. Similar methods have been employed in dealing with the fats and lipoids of the cancer cell and tissues. The idea or principle underlying treatment by these extracts is stimulation of tissue lipolytic activity with destructive action on the fats and lipoids of the cancer cell, as in the case of tuberculosis, on the fats and lipoids of the tubercle bacillus.

I am, Sir, yours faithfully,

J. A. SHAW-MACKENZIE, M.D. Lond.

London, June 30th, 1923.

DELAY IN GIVING DIPHTHERIA ANTITOXIN.

To the Editor of THE LANCET.

SIR,—All medical officers of health will agree with Dr. F. F. Caiger that frequently in fatal cases valuable time is lost by the practitioner. In 17 fatal cases of diphtheria occurring in Brighton during 1921 and 1922 the time lost by the doctor failing to diagnose the condition is shown in the following table:—

Doctor saw child on ..	2nd	3rd	4th	5th	6th	7th	
Patient had antitoxin on	3rd	3rd	4th	5th	7th	9th	day of illness.
	4th	3rd	4th	6th	—	—	
	5th	3rd	—	—	—	—	
	7th	4th	—	—	—	—	
	15th	5th	—	—	—	—	
	—	5th	—	—	—	—	

There is little doubt from a study of the table that the case mortality of diphtheria can be greatly reduced by prompt diagnosis and immediate removal of the patient to hospital. In Brighton probably one-third of the deaths could have been avoided; assuming the same conditions for the whole of England and Wales the annual loss due to lack of prompt diagnosis by the doctor is some 1800 lives. When one considers that diphtheria in the child is easy to diagnose, also that negative swab results give little help, the folly of awaiting swab results is apparent.

My own conclusions are: (1) It is the duty of general practitioners to acquaint themselves with the easily-grasped *clinical signs of* diphtheria and the duty of those controlling fever hospitals to give opportunity to the general practitioner to see typical cases of the disease; (2) it is doubtful if local authorities should accept swabs for the diagnosis of acute throat conditions in children.

I am, Sir, yours faithfully,

DUNCAN FORBES,
Medical Officer of Health, Brighton.

July 3rd, 1923.

R.A.M.C. MEMORIAL IN DUBLIN.—On July 4th Sir John Goodwin, Director-General of the Army Medical Service, unveiled in St. Patrick's Cathedral, Dublin, a memorial to the officers and men of the Royal Army Medical Corps who fell in the late war. The memorial is a marble tablet, a replica of that erected some months ago in Westminster Abbey. There was a large attendance at the unveiling ceremony.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful :—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part I., Physics and Electrotechnics.—Hubert O. Gunewardene, Richard Hayes, and Harold K. G. Hodgson.

Part II., Radiology and Electrology.—Narayan Mahadev Bodas, Lionel R. G. de Glanville, Malcolm Frizell, Hubert O. Gunewardene, William H. Hastings, Richard Hayes, Mahadev Dattatraya Joshi, Anna T. Kellock, Gabriel J. Luyt, Margaret J. Moir, Jessie E. Sheret, Sorab Byramji Warden, and Edward V. Whitby.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates were successful :—

DEGREE OF M.D.

A. V. Campbell and S. M. A. Faruki.

DEGREES OF M.B. AND CH.B. (HONOURS).

Class I.—D. Macfarlane (distinction in Obstetrics and Surgery).

Class II.—F. Earlam and T. J. Kirkpatrick (distinction in Obstetrics), J. Roberts (distinction in Medicine), and A. Tumarkin (distinction in Surgery).

FINAL EXAMINATION FOR DEGREES OF M.B. AND CH.B.

Part III.—B. Abelman, A. R. D. Adams, J. Berkson, R. W. Brookfield, T. L. Bulmer, Hilda Cantrell, W. J. B. Chidlow, R. G. Cooke, V. C. Cornwall, I. H. Davies, Hilda M. Davis, J. O. Edwards, D. P. Finn, N. D. Fraser, J. R. Griffiths, S. Hesselberg, Elizabeth Hunt, T. Knowles, W. J. Laird, D. A. Levin, C. B. Lewis, Eileen M. Lloyd, Mary M. McMillan, P. Malpas, J. H. Moorhouse, Beatrice M. Niven, T. V. O'Brien, C. H. Owen, J. D. O'M. Poole, Gertrude E. Pugmire, E. L. Roberts, Dorothea W. Rogers, J. F. D. Shrewsbury, E. R. Smith, Helen Standring, Dorothy A. Taylor, H. A. Thomas, E. J. Whymark, H. P. Widdup, A. G. Wilkinson, E. B. Wilkinson, J. Williams, and Mary G. T. Williams.

Part II.—B. E. Acland (distinction in Public Health), M. M. F. Arthur, C. B. Bamford, P. D. Barling, E. C. Benn, R. V. Berrington, C. H. Bradley (distinction in Public Health), R. S. Brock, Helen S. H. Brown, Alison M. Brummitt, J. W. Cowen, N. Cresswell, M. M. Datnow, Edwina M. Davies, Eileen N. Deane, W. T. Donovan, W. H. Ellam, W. Emdin, E. A. R. Evans, F. R. Faux, H. W. Fell (distinction in Forensic Medicine and Toxicology and Public Health), H. R. Fisher, M. Fisher, C. G. Foxcroft, F. F. Fuller, G. A. Fulton, G. A. Garrett, J. Gaughan, H. Gobie, M. Godwin, J. Graham, T. A. Griffiths, Dorothy M. Hanson, T. Hare, A. D. Harper, F. C. S. Hinsbeeck, Fannie S. Holt, S. Howard, J. E. Howie, G. P. Huws, Bertha H. Irvine, F. P. Irvine, Elvy I. Johnstone, C. P. Jones, R. W. Jones (distinction in Forensic Medicine and Toxicology and Public Health), R. C. Jones, R. Jones (distinction in Forensic Medicine and Toxicology), D. Katz, G. F. Kinder, J. Leggate, W. E. Lishman, J. H. M. Little, G. Lowe, W. A. McCurdy, G. Macdonald (distinction in Forensic Medicine and Toxicology), Margaret S. Macdonald, E. Miles, D. H. Mills, E. P. Moloney, G. A. Moulden, A. Newton (distinction in Forensic Medicine and Toxicology), J. R. R. Nicholas, J. R. Oddy, J. J. O'Donovan, F. C. O'Mara, A. Oserovitz, E. R. S. Owen, R. D. Owens, A. Pool, R. J. Prydderch, Gwendolen H. ff. Roberts, J. T. C. Roberts, E. Rowlands, E. Scott, J. A. Scott, P. Strelitz, G. V. L. Taylor, A. C. Terry-Thompson, J. H. Thompson (distinction in Public Health), J. J. du Toit (distinction in Forensic Medicine and Toxicology), Marjorie A. Unsworth, H. S. Welton (distinction in Forensic Medicine and Toxicology), T. W. White, and Gwennie Williams (distinction in Forensic Medicine and Toxicology).

Part I.—Mary G. B. Allen, C. G. Foxcroft, T. Hare, A. D. Harper, R. W. Jones (distinction in Pathology), T. S. L. Jones, Rebecca Katz, W. A. McCurdy, J. McWilliams, J. R. Mitchell, F. C. O'Mara, R. D. Owens, P. J. Rogers, J. H. Thompson, and Mabel J. Watterson.

DIPLOMA IN PUBLIC HEALTH.

Doris Brown, Matilda L. Craig, Jeannie P. Dunn T. K. Hughes, W. McMullen, and T. R. Roberton.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful :—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—Thomas W. May (high marks), Paul H. N. Labuschagne (high marks), William C. Somerville-Large (high marks), Isidore Rosin, James Dick, William Gallaugher, James V. Morris, William B. Roantree, Eric T. S. Rudd, Oliver Chance, William P. E. McIntyre, Thomas G. B. Crawford, William A. Hopkins, Joseph R. Gregory, and O'Donel T. D. Browne.

Part II., Medicine.—Marjorie F. Sibthorpe (high marks), Victor O. McCormick (high marks), Paul J. Grobler, Morris Cohen, Benjamin W. D. Fayle, Francis J. O'Meara, Charles T. MacCarthy, William T. Hogan, William E. Hutchinson, Mossy Jaffe, James E. Deale, Frederick T. Easby, Richard A. D. Pope, William L. Duncan, Isobel G. Smith, Henry M. Martin, Harry Ruben, Harold Lewin, Reginald A. Dench, Richard C. L. Griffiths, Martha Reid, Albert V. Foster, Cecil H. Keller, Solomon Narunsky, Bertha H. Lawler, James J. O'Grady, Frederick G. Brown, Henry W. L. Dale, and Isabella H. Speedy.

Surgery.—Robert T. Jackson (high marks), Benjamin W. D. Fayle, Francis J. O'Meara, Joseph E. Eliason, Joseph A. Gaynor, John M. Mounsey, Marjorie F. Sibthorpe, Richard A. D. Pope, Hyman S. Roseman, Maria E. Wagener, Reginald A. Dench, William S. Dixon, Philipp F. H. Wagner, Bernard Morris, William E. Hutchinson, Wilfrid E. C. Wynne, Arthur Darlington, Asher Asherson, William F. Whaley, Gladys Weatherill, Frederick T. Easby, Dermod H. F. Milmo, Dorothy C. H. Dorman, Lazarus Heyman, Alice M. A. Downing, Robert S. McElroy, Richard C. L. Griffiths, Henry L. Hanna, Rupert L. Hill, James R. Wills, Siegfried D. Gabbe, Joseph C. Byrne, Eric C. Downer, Willem J. Janse van Rensburg, Charles T. MacCarthy, Solomon Narunsky, Pieter C. du Plessis, Charles Gordon, Albert V. Foster, Tobias Freedman, Dorothy I. Henry, Herbert Kohlberg, Israel Marin, Laurence Phillips, Charles R. Hillis, Julius Kruger, Jack A. Levitt, and Joseph M. O'Connor.

Midwifery.—John J. Laing (high marks), Maynard A. Gerrard (high marks), Henry Isaacson (high marks), James E. Deale, William F. Whaley, Rudolf Schaffer, Robert F. J. Henry, William L. W. Smith, Noel G. McAuliffe, Thomas G. Wilson, Gordon Purdy, Gerrard A. Sloan, Wallace R. Aykroyd, Evaline E. Mooney, Lucy M. Joly, James J. O'Grady, Isaac J. Isaacson, Mossy Jaffe, Charles Gordon, Kathleen D. Murison, Norman M. Greeves, Philip P. van der Merwe, Jan Andreas du Toit, Isabella H. Speedy, Jack M. Gordon, James J. FitzGerald, Willem J. Janse van Rensburg, and Robert L. C. Fisher.

DIPLOMA IN PUBLIC HEALTH.

Part I., Chemistry, Bacteriology, Physics, and Meteorology.—Edmund C. Smith and Elizabeth Killian.

Part II., Sanitary Engineering, Practical Sanitary Report, Hygiene and Epidemiology, Vital Statistics, and Public Health Law.—Edmund C. Smith, Dorothy K. M. Henry, Elizabeth Killian, and Catherine A. Goggin.

UNIVERSITY OF MANCHESTER.—The following appointments have been made :—Lecturer in Botany: Mr. John Walton. Lecturer in Bacteriology: Dr. G. Selby Wilson. Assistant Lecturers in Chemistry: Mr. E. L. Hirst and Mr. G. N. Burkhardt.

THE LATE DR. G. L. H. REVILL.—George Leslie Howard Revill, who died on July 6th, received his medical education at Charing Cross Hospital and at Vienna, becoming M.R.C.S. in 1890. He was well-known in Lincolnshire, having a wide practice centred at Heighington, and being very popular alike with his patients and with the members of the many public bodies and friendly societies with whom he held appointments. He was a devout churchman and in politics an ardent Conservative, but he formed enduring friendships with many whose views differed widely from his own. His widow and a son survive him.

ROYAL SOCIETY OF MEDICINE: SECTION OF COMPARATIVE MEDICINE.—On July 6th, under most promising auspices, a new section of this society was formally constituted under the title of the Section of Comparative Medicine, the membership of which is open to duly qualified veterinary surgeons as well as to practitioners of human medicine. Considerable advance has already followed the coöperation of workers on the two sides of medicine, and it is hoped that the constant interchange of views at the meetings of this section will lead to even more rapid progress. The new section, the foundation of which is largely due to the good offices of Prof. F. T. G. Hobday, starts with a strong council, half representing human medicine and half veterinary medicine, with Sir Clifford Allbutt, who has for many years advocated the rapprochement which has now been accomplished, as president. Vice-presidents include Sir Layton Blenkinsop, Lieut.-Colonel J. W. Brittlebank, Sir William Hale-White, Prof. F. T. G. Hobday, Sir William Leishman, F.R.S., Sir John Moore, Sir Leonard Rogers, F.R.S., and Mr. G. H. Wooldridge. Meetings for papers and discussions will be held next session on the fourth Wednesday of each month at 5.30 P.M.

POSTPONEMENT OF THE INTERNATIONAL CONGRESS OF OPHTHALMOLOGY (1925).—The Committee of British Ophthalmologists, appointed to organise an international congress in 1925, finds with regret that it is unable to do so in accordance with the conditions under which the British invitation was accepted by the Washington Ophthalmological Congress in 1922. It will be remembered that at Washington it was decided that the next congress should be strictly international and that German should be one of the official languages. The Committee has since been informed that the Société Française d'Ophtalmologie, the Société d'Ophtalmologie de Paris, and the Société Belge d'Ophtalmologie have passed resolutions to the effect that they feel themselves unable to participate in a congress if Germans are invited. The Committee is of opinion that to proceed with the congress in these circumstances would tend to perpetuate a schism in the ranks of ophthalmology and militate permanently against the progress of the science which all desire to promote. The Committee has therefore reluctantly decided to postpone the congress.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—The annual general meeting of the society will be held at 11, Chandos-street. Cavendish-square, London, W. 1, on July 20th, at 5.30 P.M., when a paper will be read by Mr. Frank Kidd on Vasostomy for Chronic Seminal Vesiculitis (A New Technique).

FELLOWSHIP OF MEDICINE.—A complete course of lectures on medical and surgical diseases of children will be given by all the members of the staff at the Royal Waterloo Hospital from July 16th to August 3rd. In addition to the lecture-demonstrations candidates will have the privilege of attending the out-patient department, wards, and operations. A special course in dermatology will be given by members of the staff at the Hospital for Diseases of the Skin, Blackfriars, from July 16th to the 28th inclusive. Instruction will be given in the out-patient department every afternoon from 2.30 P.M., and a special demonstration on interesting selected cases will be held at 4 P.M. on July 16th and July 25th. The course will also include a venereal clinic on Tuesday and Friday each week from 5.30 to 7 P.M. The fees for these courses are 3 guineas and 2 guineas respectively. Application for copies of the syllabus and tickets of admission should be made to the Secretary to the Fellowship of Medicine at 1, Wimpole-street, London, W. 1.

SIXTH CONGRESS OF THE SOCIÉTÉ INTERNATIONALE DE CHIRURGIE.—The Congress will be held in London from July 17th to 20th; the scientific sessions will be held at the Royal Society of Medicine, 1, Wimpole-street, W. 1, and the definitive programme is as follows:—July 16th: 2 P.M., meeting of International Committee. 17th: 11 A.M., opening by the Prince of Wales. speeches by Lord Curzon, Mr. Neville Chamberlain. and others. and address by Sir William Macewen (president); 2 P.M., discussion: Surgery of Endocrine Glands (Thyroid excluded). 18th: 9.30 A.M., discussion: Arthroplasty; 2 P.M., operations at hospitals. 19th: 9.30 A.M., discussion: Late Results of Peripheral Nerve Injuries: 11.30 A.M., general meeting: 2 P.M., operations. 20th: 9.30 A.M., discussions: Vaccine and Serotherapy (Tetanus excluded), and Operative Shock; 2 P.M., operations; demonstrations on vaccine-therapy by Sir Almroth Wright at St. Mary's Hospital. Entertainments:—July 16th: Evening reception by the University of London; 17th: evening reception by the President; 18th: official luncheon by H.M. Government for National Delegates; evening reception by the Lord Mayor, Mansion House. 19th: 4–6 P.M., reception by the President of Royal College of Physicians: 9–12 P.M., reception by President of Royal College of Surgeons; 20th: Annual banquet of Society. Secretaries of the Congress. Sir D'Arcy Power and Mr. J. S. H. Roberts (delegate for British Isles).

Mr. Henry Kimpton announces the publication of the following: "The Tonsils: Faucial, Lingual, and Pharyngeal, with some account of the Posterior and Lateral Pharyngeal Nodules," by Dr. Harry A. Barnes (second edition): "Practical Local Anæsthesia and its Surgical Technic." by Dr. Robert Emmett Farr; "Cerebro-spinal Fluid in Health and in Disease," by Dr. Abraham Levinson, B.S. (second edition)' "Tonsillectomy by Means of the Alveolar Eminence of the Mandible and a Guillotine," by Dr. Greenfield Sluder; "Local Anæsthesia in Dental Surgery," by Mr. F. St. J. Steadman, L.D.S. Eng.; "Epidemiology and Public Health: A Text and Reference Book for Physicians, Medical Students, and Health Workers," by Dr. Victor C. Vaughan (vol. ii. ready, vol. iii. in preparation); "Clinics and Collected Papers of St. Elizabeth's Hospital, Richmond, Virginia, 1922"; and "Collected Papers from the Washington University School of Medicine, 1921."

CONDITION OF PRISONS AND INTERNMENT CAMPS IN THE IRISH FREE STATE.—The Free State Government has issued a copy of the report of the International Red Cross Commission on the treatment of prisoners in the hands of the Government. It is stated that the Free State Government welcomed an investigation by an independent and competent body, in view of the propaganda that had been conducted. alleging improper treatment of prisoners. Mr. R. Haccius, a delegate from the Red Cross Commission, visited the principal internment camps in the Free State. He stated that he found the treatment of the prisoners devoid of hostile spirit, and although the Government refused to grant the prisoners the status of "prisoners of war," in reality it treated them as such. Nowhere did he find a wounded or sick prisoner left without medical treatment. On the contrary, he found everywhere a carefully organised medical service. The serious accusations made on this subject appeared to the delegate to be unfounded. He noted that the buildings of the old North Dublin Union were in course of alteration for the reception of the women detained at Kilmainham. and these buildings with the surrounding gardens would fulfil all desirable hygienic conditions. The delegate had instructions to exclude inquiry into individual complaints. He noted that searches had taken place in various private hospitals, but the working of these hospitals had not been interfered with. The complaints regarding sanitary conditions and food in the camps were unfounded. Mr. Haccius then gives a detailed report on the various camps and prisons visited. While satisfied generally with the sanitary conditions, he noted congestion in Mountjoy Prison, where there were in some cases three prisoners in cells which should not hold more than two. He speaks favourably of the medical arrangements everywhere. and noted at the Curragh Camp that "the patients seemed to be very grateful to the doctors for their devoted care and attention."

ROYAL VICTORIA HOSPITAL, BELFAST.—At a meeting of the board of management on July 4th the retirement of Prof. Thomas Sinclair after 38 years' service was the subject of several speeches expressive of the high esteem in which he is held, and of the appreciation by the board of his work as surgeon and teacher. An appropriate resolution was moved by Lieut.-Colonel Mitchell, seconded by the Rev. W. A. Watson, supported by Mr. W. Carson, J.P., and carried with much enthusiasm. The chairman of the board (Prof. J. A. Lindsay) described Prof. Sinclair as one of the pillars of the Royal Victoria Hospital and one of the mainstays of the Belfast Medical School, whose reputation at home and abroad he had done so much to promote and to enhance. Prof. Sinclair is succeeded on the staff by Mr. S. T. Irwin. Mr. H. P. Malcolm was elected assistant surgeon to the hospital.

AN ASYLUM IN INDIA.—The annual statements of the Central Provinces Lunatic Asylum naturally reveal a number of features which are strange to similar work in this country. The hospital accommodates about 400 insane, but the number had to be reduced considerably during the year owing to the scarcity of water. Mania and melancholia are the prevalent types of insanity; no cases of general paralysis. and only one of mental disease attributable to syphilis, were admitted during the year. On the other hand, cannabis indica plays an ætiological part which is unfamiliar to us; tuberculosis appears to be fairly common, and infection with ankylostomes was present in 16 per cent. of the admissions. A radical change in the diet scale has been introduced, and among other improvements which have been sanctioned by Government is the provision of proper accommodation for private patients.

UNIVERSITY COLLEGE, LONDON.—Viscount Chelmsford, chairman of the University College Committee. with Sir Gregory Foster, the Provost of University College, the Deans of the College Faculties, and the tutor to women students, held a reception last Saturday afternoon. July 7th. at which the whole of the College buildings were open for inspection. One object of the reception was to give all old students of University College an opportunity of re-visiting the College and of seeing some of the more recent extensions which have taken place. and in particular the new building for anatomy and the extension of the physiology and pharmacology buildings, forming the Rockefeller Benefaction, opened by the King on May 31st. University College Hospital and University College Hospital Medical School were open throughout the afternoon. About 3000 persons were present. including many headmasters and headmistresses of schools and others connected with various branches of education.

Sir Henry Gray, who is leaving Aberdeen to take up his new post as chief surgeon of the Royal Victoria Hospital, Montreal, was entertained by members of the medical profession to dinner at the Palace Hotel, Aberdeen, on June 27th, Mr. J. Scott Riddell in the chair. In proposing the health of the guest, Mr. Riddell spoke of other Aberdonians who had crossed the Atlantic to professorial chairs in Canada and the United States, and in the course of an eloquent tribute to Sir Henry Gray referred to him as one who would spread the light and enhance the reputation of the medical school of Aberdeen. Sir Henry Gray, in replying. recalled the commencement of his professional work under Sir Alexander Ogston. and his long association with many of those present. He spoke of his long consideration of the invitation to go to Montreal. and of the restlessness, increased by the war. which had helped him to come to his decision. In the light of the nature of his new work. of the environment in which it would be set, and the possibilities of the future in such a progressive place, he felt that it was one of the most desirable positions in the surgical world. Later on in the course of his reply Sir Henry Gray spoke of his great indebtedness to the nursing profession for the very high order of help he had received from them.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JULY 4TH.

Industrial Diseases.

Mr. D. G. SOMERVILLE asked the Minister of Labour whether, in view of the request for the inclusion of eyesight failure in the Workmen's Compensation Act, his department possessed any reliable record showing how the individual senses were affected by particular industries, and whether in such cases steps were taken to differentiate at any stage between failure due to advancing years and failure due to conditions of work.—Mr. LOCKER-LAMPSON (Under Secretary to the Home Office) replied : The department is in possession of a great deal of information as to diseases and affections which are caused by particular industries and processes, but so far as regards failure of eyesight, such as short-sightedness or other kinds of eye-strain, it would not be possible to differentiate between the effects of the conditions of work, advancing years, and other possible causes.

Viscount CURZON : Does the hon. gentleman's answer apply to the case of railwaymen disabled by injured eyesight? —Mr. LOCKER-LAMPSON : As my noble and gallant friend knows, certain afflictions of the eye are already included under the Act of 1906 and they are being added to.

Skimmed Dried Milks.

Mr. HURD asked the Minister of Health the result of his consideration of regulations for the proper labelling of skimmed dried milks as unfit for children.—Mr. NEVILLE CHAMBERLAIN replied : Draft regulations dealing with this matter have been prepared in my department and I am causing them to be forwarded to the other departments concerned as a preliminary to discussion.

Mr. HURD : Is there any necessity in this matter to consult other countries seeing it is purely a domestic affair of our own ?—Mr. CHAMBERLAIN : So far as I am aware it will not be necessary.

Approved Societies and Voluntary Hospitals.

Sir EDWIN STOCKTON asked the Minister of Health whether, in view of the amount of disposable surpluses of approved societies under the National Health Insurance Act, he would consider the desirability of introducing legislation for the allocation of funds therefrom for the hospital maintenance of insured patients, seeing that such a policy would materially contribute towards meeting the total annual deficiency of the voluntary hospitals.—Mr. NEVILLE CHAMBERLAIN replied : It is open to any approved society having a disposable surplus on valuation to devote the whole or part of such surplus to making payments to hospitals or convalescent homes towards securing the maintenance and treatment therein of members of the society, and out of the surpluses on the first valuation a sum of £979,000 was set aside for this purpose by certain societies in England in respect of the period from July, 1921, to June, 1926. The selection of the additional benefits to be provided by a society for its members rests with the members themselves, and I do not think it desirable that legislation should be introduced to make it compulsory on every society having a disposable surplus to allocate the whole or part of the surplus to any particular additional benefit.

Mr. GERALD HURST asked the Minister of Health whether he was aware of the hardship caused by the disability which now debarred voluntary hospitals from sharing in surplus funds which had accumulated under the National Health Insurance Act, and that the Manchester Royal Infirmary spent about £70,000 a year in maintaining nearly 5000 persons insured under that Act without drawing any substantial contributions from their approved societies ; and if he would consider so amending the law that maintenance and treatment at voluntary hospitals might be included among the additional statutory benefits to be provided from disposable surplus funds.—Mr. NEVILLE CHAMBERLAIN replied : There is no such disability as is mentioned in the first part of my hon. friend's question, and the making of payments towards the cost of the maintenance and treatment of insured persons at voluntary hospitals is already included amongst the additional benefits which may be provided by approved societies from their disposable surplus funds. Such payments are, in fact, being made by a number of societies with a total membership of over 7,000,000 insured persons. The second part of the question does not therefore arise.

Poor-law Midwifery Fees.

Lieut.-Colonel FREMANTLE asked the Minister of Health if he was aware that Poor-law midwifery fees had not been revised since 1847; and whether he would take steps to bring them into line with the fees ruling at present for services of a similar nature.—Mr. NEVILLE CHAMBERLAIN replied : It is true that the Order of 1847 has not been revised, but in a number of cases special arrangements between the guardians and their medical officers as regards midwifery fees have already been approved. I will, however, consider the question of the revision of this part of the order.

Patent Medicines Legislation.

Lieut.-Colonel FREMANTLE asked the Minister of Health if it was proposed to introduce a Bill to give effect to the recommendations of the Select Committee on Patent Medicines, proposals for which were agreed with the parties concerned in 1920.—Mr. NEVILLE CHAMBERLAIN replied : In the present state of business the Government cannot undertake to introduce legislation on this subject during the present session.

Pasteurised Milk.

Mr. ADAMS asked the Minister of Health whether he was aware that, owing to the Milk (Special Designations) Order, 1923, modifying previous orders regarding pasteurisation, it was possible for milk to be sold to the public after having been subjected to repeated heating processes, thus having the major portion of its nutritive value destroyed ; and whether he would take the necessary steps to ensure that such reheated milk should not be retailed to the public or, if so retailed, its exact nature should be indicated.—Mr. NEVILLE CHAMBERLAIN replied : The answer to the first part of the question is in the negative. It is expressly provided in the Milk (Special Designations) Order, 1923, that the milk sold as "Pasteurised" milk shall not be heated more than once. As regards the second part of the question, I am advised that the danger arising to public health from the sale of reheated milk is not such as to justify the issue of special regulations which in present circumstances might result in restricting the supply of milk.

Vaccination and Small-pox.

Dr. CHAPPLE asked the Minister of Health what was the proportion of vaccinated to unvaccinated children of the age of 10 years and under; whether there had been any progressive change in this proportion; and what steps he proposed to take in order to safeguard the population against a possible epidemic of small-pox.—Mr. NEVILLE CHAMBERLAIN replied : It is not possible to state definitely what proportion of the children now living of the age of 10 years and under has been vaccinated. The available statistics show the numbers of children born in each year who were vaccinated within a period expiring at the end of the year following the year of birth. These statistics suggest that the proportion of children now living of the age of 10 years and under who have been vaccinated is not more than 50 per cent. I will send the hon. Member a statement giving the figures for each of the years 1912 to 1921, and showing that the proportion of vaccinations to births has fallen from 50·1 per cent. in 1912 to 38·3 per cent. in 1921. As regards the last part of the question, my department has recently circulated to sanitary authorities and boards of guardians memoranda as to the steps which should be taken on the occurrence of small-pox, and all possible assistance is rendered by medical officers of my department to the authorities of those districts in which an outbreak occurs.

Mr. TREVELYAN THOMSON asked the Minister of Health the average percentage of vaccinations to total births for the last five decennial periods and the number of cases of small-pox per 1000 of the population for the same periods.—Mr. NEVILLE CHAMBERLAIN replied : As regards the first part of the question the percentages of vaccinations to total births in the periods referred to were as follows : 1872–1881, 85·6 ; 1882–1891, 82·2 ; 1892–1901, 68·0 ; 1902–1911, 67·9 ; 1912–1921, 43·4. As regards the second part, particulars as to the total number of cases of small-pox in England and Wales are not available for any year prior to 1911. The number of cases per 1000 of the population for the period 1912–1921 was 0·004.

Replying to Mr. HURD, Mr. CHAMBERLAIN said that he was keeping a close watch upon the situation, and so far as he could see at present there was no need for special legislation.

Mr. THOMSON : Has the right hon. gentleman any information which shows whether the percentage of cases of small-pox has increased relatively to the decrease in the number of vaccinations ?—Mr. CHAMBERLAIN : Yes, undoubtedly.

Viscount CURZON : Has the right hon. gentleman any explanation with regard to the very remarkable drop in the last set of figures which he gave from 67 per cent. to 43 per cent.?—Mr. CHAMBERLAIN : I think that is due to the agitation against vaccination which has taken place in various parts of the country.

Mr. FRANK GRAY asked the Minister of Health whether he had any information indicating that a large number of cases at Gloucester had been wrongly diagnosed by officials of his department, and whether he proposed to take any steps in the matter.—Mr. NEVILLE CHAMBERLAIN replied : The answer to the first part of the question is in the negative, and the second part therefore does not arise.

Mr. SNOWDEN asked the Secretary of State for the Home Department whether his attention had been called to the difficulties put in the way of parents wishing to take advantage of the Vaccination Act, 1907, by magistrates who disapproved of exemption being granted to objectors to vaccination; and whether he would inform all magistrates sitting in open court that they must accept statutory declarations under that Act, whatever their views in respect of vaccination.—Mr. LOCKER-LAMPSON replied: Complaints are occasionally made that individual magistrates refuse to receive declarations, but they have been very infrequent. The Secretary of State has no authority to give the instructions suggested in the last part of the question, but he has repeatedly said that it is the duty of justices to take care that no unnecessary difficulties are put in the way of those desirous of exercising their statutory rights.

THURSDAY, JULY 5TH.

Tuberculosis in Scotland.

Mr. MURNIN asked the Under Secretary to the Scottish Board of Health the number of persons who died in Scotland during 1921–22 from tuberculosis.—Captain ELLIOT replied: The number of deaths in Scotland from tuberculosis was 5737 in the year 1921 and 5818 in 1922.

Small-pox and Chicken-pox.

Major Sir FREDERICK KELLEY asked the Minister of Health whether, in view of the danger that mild cases of small-pox might not be recognised as such, he would consider the issue of a statement instructing parents and others how incipient small-pox may be distinguished from chicken-pox.—Lord E. PERCY replied: My right hon. friend does not consider that the issue of such a statement would be of advantage. It is the function of the medical practitioner in attendance upon a patient to distinguish incipient small-pox from chicken-pox, and the services of the medical officer of health are at his disposal in assisting in the diagnosis of doubtful cases.

Deaths from Small-pox.

Mr. TREVELYAN THOMSON asked the Minister of Health the percentage of deaths to cases of small-pox in each of the last five years, showing separately the figures for those vaccinated and those who had never been vaccinated.—Lord E. PERCY replied: As the protection afforded by vaccination diminishes with lapse of time, I have divided the deaths of vaccinated persons into age groups. The figures are as follow:—

Percentage of Deaths to Cases of Small-pox.

Year.	Vaccinated.			Unvaccinated.
	10 years and under.	Over 10 and under 40.	40 and over.	
1918 ..	—	3·4	3·4	Nil.
1919 ..	—	0·6	3·2	20·8
1920 ..	—	1·5	8·3	13·8
1921 ..	—	—	1·0	1·5
1922 ..	—	0·4	4·1	1·6

Health Absences of School-children.

Mr. EDE asked the President of the Board of Education if he would be prepared to recognise absences of children from elementary schools to receive sanatorium, hospital, or other medical treatment when such absences were ordered by the school medical officer or the medical officer of health as ranking with those specified in paragraph 23 (c) of Schedule 4 of the Code and would allow them to count as attendances under Article 44 (*h*) of the Code, thereby removing an anomaly that became increasingly apparent with the growing vigilance of the school medical service of the country.—Mr. E. WOOD replied: The suggestion made in the question raises points of financial and administrative importance, and I cannot commit myself to reconsider the existing arrangements at the present time.

Pensioners and Medical Treatment.

Mr. ROBERT YOUNG asked the Minister of Pensions what was the number of pensioners who were receiving medical treatment, how many of these were in military hospitals, how many were in general hospitals, how many were receiving home treatment, and of the total number how many were undergoing treatment which prevented them being employed in any occupation.—Major TRYON replied: There are approximately 76,500 officers and men receiving treatment at the cost of my department, of whom about 41,600 are prevented by the treatment from following their occupations. Of the total mentioned, 18 are in military hospitals, 3650 are in general hospitals, and 9300 are receiving home treatment. These figures do not include men receiving treatment, without allowances, from their panel practitioners, of whom I have no record.

MONDAY, JULY 9TH.

Infantile Mortality.

Mr. A. V. ALEXANDER asked the Minister of Health the number of deaths of children for each year from 1914 to 1922, giving separate figures for illegitimate children and covering the ages of under 12 months, over 1 year and under 2 years, and over 2 years and under 3 years respectively.—Mr. CHAMBERLAIN replied: No figures respecting deaths of illegitimate children of 1 to 2 years or 2 to 3 years of age are available prior to 1919, when they were first abstracted. The rest of the required figures are given below:—

Deaths: England and Wales.

—	Under 1 year.		1–2 years.		2–3 years.	
	Total.	Illegitimate.	Total.	Illegitimate.	Total.	Illegitimate.
1914 ..	91,971	7,712	24,967	—	10,072	—
1915 ..	89,380	7,369	30,279	—	12,482	—
1916 ..	71,646	6,000	20,009	—	8,611	—
1917 ..	64,483	7,474	20,296	—	9,724	—
1918 ..	64,386	7,694	26,447	—	14,955	—
1919 ..	61,715	7,237	14,124	1,131	7,658	469
1920 ..	76,552	7,017	14,741	1,162	6,100	364
1921 ..	70,250	6,115	15,636	1,041	4,991	336
1922 ..	60,121	4,736	18,948	1,064	8,678	453

Illegitimate Births.

Mr. A. V. ALEXANDER asked the Minister of Health the number of children born in each of the years from 1914–22, giving the numbers separately for illegitimate births.—Mr. CHAMBERLAIN replied: The numbers of children born (total and illegitimate) for each year 1914 to 1922 are shown below:—

Births: England and Wales.

Year.	Total.	Illegitimate.	Year.	Total.	Illegitimate.
1914	879,096	37,329	1919	692,438	41,876
1915	814,614	36,245	1920	957,782	44,947
1916	785,520	37,689	1921	848,814	38,618
1917	668,346	37,157	1922	780,124	34,138
1918	662,661	41,452			

TUESDAY, JULY 10TH.

Scottish Public Health Authorities.

Mr. DUNCAN MILLAR asked the Under Secretary to the Scottish Board of Health whether, in view of the widespread anxiety and apprehension created by the Report of Scottish Board of Health Consultative Council recommending the abolition of the parish councils in Scotland and of the smaller burghs and public health authorities, he could give an assurance that no steps were at present contemplated to give effect to the views of the Consultative Council, and that the fullest opportunity would be afforded to the parish councils and burghs and other public health authorities to express their views before any decision was arrived at.—Captain ELLIOT replied: I am now aware that the publication of the Report referred to has created anxiety and apprehension, but the hon. Member may rest assured that no decision will be taken on the matters referred to without full opportunity to the local authorities mentioned to express their views.

Selection of R.A.M.C. Officers.

Mr. BECKER asked the Under Secretary of State for War if all officers in the Royal Army Medical Corps eligible for selection to the higher ranks were personally interviewed by the selection board; and could he give his assurance that none would be passed over who had not been so interviewed.—Lieut.-Colonel GUINNESS replied: The answer is in the negative. I do not think that a system of inviting officers to attend and make out a case for their own promotion would be at all satisfactory, even if all the officers concerned were always available for such attendance, which they are not. It rarely happens, however, that an officer is not known personally to the majority of the selectors.

Appointments.

DENT, HELEN P., M.B., B.S. Lond., has been appointed Maternity and Child Welfare Medical Officer, Leicester.

GALBRAITH, S. N., M.B., Ch.B. Glasg., Medical Officer of Health for South-West Kent.

GIMBLETT, CHARLES LEONARD, M.D. Camb., F.R.C.S. Eng., Hon. Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

KIEP, W. H., M.B., Ch.B. Glasg., an Hon. Ophthalmic Surgeon to the Royal Ear and Eye Hospital, Bradford.

Certifying Surgeons under the Factory and Workshop Acts: **MCNAUGHTAN, W.**, M.B., Ch.B. Edin. (Hawes); **DOBSON, J. G.**, M.B., Ch.B. Edin. (Chirnside); **LOWRY**, M.R.C.S., L.R.C.P. Lond. (Brentford and Ealing); W. B., L.R.C.P. & S. Edin., L.R.F.P.S.Glasg. (W

Salford Royal Hospital.—Honorary Dental Surgeon.
Stoke-on-Trent County Borough.—Asst. M.O. £500.
Tiverton Hospital, Devon.—H.S. £100.
Wandle Valley Isolation Hospital.—R.M.O. £400.
West African Medical Service.—M.O. £660.
Windermere.—Ethel Hedley Hospital for Crippled Children. H.S. £150.
Wolverhampton and Staffs Hospital.—H.S. £150.
Wrexham Infirmary.—H.S. £150.

Births, Marriages, and Deaths.

BIRTHS.

BARRY.—On June 24th, at Hyde Park Barracks, the wife of Captain S. J. Barry, R.A.M.C., of twin sons.

KELLOCK.—On July 4th, at Upper Wimpole-street, W., the wife of the late T. H. Kellock, M.D., M.Ch., F.R.C.S., of a son.

LONGSTAFF.—On July 3rd, at Picket Hill, near Ringwood, the wife of Dr. T. G. Longstaff, of a daughter.

MADGE.—On July 4th, at Brookside, Ashbourne, Derbyshire, the wife of Dr. Quintus Madge, of a son.

MORLEY.—On June 28th, at "Grasmere," Mill Hill, N.W., the wife of Allan Morley, M.B. Lond., of a daughter.

MARRIAGES.

FERRIER—CONEY.—On June 26th, at Studland Church, Swanage, David Ferrier, M.D., of Dunstable-road, Luton, to Adeline Maud Coney, daughter of the late S. W. Coney, Bournemouth.

POSTLETHWAITE—CLAYTON.—On July 3rd, at St. Augustin's Church, Bournemouth, William Barry Postlethwaite, M.B., M.C., to Barbara Clayton, the younger daughter of Dr. and Mrs. A. J. Clayton, of Wimborne-road, Bournemouth.

DEATHS.

BURY.—On July 4th, at Galtee House, Foxley-lane, Purley, Surrey, George Bury, L.R.C.P., M.R.C.S., aged 93.

KIRBY.—On July 3rd, at Bromley Lodge, Bromley, Kent, Dr. Albert Edward Kirby, M.R.C.S. Eng., aged 74.

MURIEL.—On July 3rd, at Glenfield, Whitehaven, George John Muriel, J.P., M.R.C.S. Eng., in his 81st year.

SAYER.—On July 7th, after a prolonged illness, Dr. Ettie Sayer, M.B., B.S., of Ennismore-gardens, W.

STEWART.—On July 3rd, at his home, Yeoveney, Alexandra-road, Watford, suddenly from heart failure, Alexander Brodie Seton Stewart, late of Leeds, Lieut.-Colonel, R.A.M.C.(T.), O.B.E., T.D., Order of St. Sava of Serbia.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

FURTHER NOTES ON SMALL-POX DIAGNOSIS.

BY W. McCONNEL WANKLYN, B.A. CAMB., M.R.C.S. ENG., D.P.H.

To include within a few lines, such as those published in THE LANCET on July 7th, all that should be understood upon this subject is clearly impracticable; the following additional notes may therefore be useful. As the subject is one of the humblest of our professional duties and one which we are endeavouring to get rid of as soon as possible, so also is it one of absolutely fundamental importance for each one of us to tackle until our island is cleared of small-pox beyond any possibility of its return. The laity are keenly alive to the financial risks; when those risks mature they require someone's blood. That is the fact. Many of us may never have a suspected case; some are dead certain to have one or more; and yet others, if unprepared, may thereby be ruined. Wherefore the main point and kernel of interest for us in the matter is not any clinical, academic, or epidemiological feature per se; we have no time for such; but it is this. Can I be reasonably sure of at least challenging any single case of this odious disease that may drift my way? It is with such a query in mind that your readers may be pleased to glance at the notes of the following case, placed at my disposal by one of the various colleagues with whom I have had the pleasure of seeing cases in consultation. An effort is being made to file and reproduce such cases for mutual guidance, and any other notes of the kind will be welcomed. Only those points have been brought out which are likely to be of direct value to the reader, when faced with an awkward case.

An Awkward Case.

The case was that of S. S., a female, aged 6. It was obviously either small-pox or chicken-pox. A count of the spots showed as follows:—Right hand, 5; right forearm, 1; right arm, 10; right foot, 3; right leg, 4; right thigh, 15; left foot, 2; left leg, 4; left thigh, 11; face, 15; front of trunk, 50. This, taken with the superficial and peculiar character of the vesicles, and the absence of initial or constitutional symptoms, was sufficient to establish a diagnosis of chicken-pox. There remained for consideration the rash on the left upper extremity. This was very remarkable. On the left hand were 14 lesions, on the left forearm 4, on the left arm 10. It was the remarkably thick crop on the left hand which led to this case arousing a suspicion of small-pox. But when the facts were gone into this was noted. Previous to her attack of chicken-pox, the child had been suffering from an acutely septic condition of the left hand, for which she had been attending hospital, and it was upon this inflamed area that a numerous and well-developed crop of vesicles had settled.

Herein we come upon a phenomenon which, well known in small-pox, is also present in chicken-pox to a less degree, that is the selection by the rash of irritated surfaces. This much at least comes out as noteworthy, that that factor itself is not pathognomonic of small-pox. I have seen numerous remarkable instances of the same phenomenon in chicken-pox. In one recent case the outline of the garters below the knees in an adult was conspicuously picked out by the rash of small-pox. I have also seen scratch marks picked out by the rash of chicken-pox and other similar sites of irritation, such as those on the skin of ill-tended children.

Four Main Criteria.

It comes to this; that there is no single golden rule, no measuring tape or touchstone by which we can say: This is chicken-pox; that is small-pox. In nine cases out of ten in which the diagnosis rests between chicken-pox and small-pox in an adult, a count of the spots on the upper extremities will correctly point to the truth. In the tenth, it may not so point, as was demonstrated to me by a case only two or three days ago. In children there is more variety in the distribution of the rash of chicken-pox than there is in adults. It more often varies from the accepted type. In all the cases, however, which I can recall, the degree of prostration has been a valuable sign. That is seldom so marked in any case of chicken-pox as it is in small-pox; and it is a remarkable point that where a copious rash due to chicken-pox occurs in a patient, in that patient there is commonly no such degree of prostration as almost invariably occurs in an attack of small-pox of corresponding degree. The four main points which I have consistently found to be most useful in my work are: (1) The distribution of the rash; (2) the degree of prostration; (3) the relative depth of the lesions in the skin; and (4) the maturation of the lesions.

There seldom occurs a case in which the evidence drawn from the facts grouped under these four heads and duly weighed fails to yield a correct decision. And such evidence has this further advantage, that it is readily accessible.

THE WELFARE OF MENTAL PATIENTS.

Two gatherings, important in relation to the welfare of mental patients, were held in London on July 12th.

The Mental Hospitals Association

met at the Guildhall. Among the items on a full agenda was a report of the Executive Committee commenting on the Mental Treatment Bill recently introduced. It is accepted that the clauses, which are not in effect so far-reaching as was desired by the Association, contain provisions which, when passed into law, cannot fail to prove beneficial to those suffering from incipient or recurring mental illness. The Bill has received the careful consideration of the Committee which has addressed a communication to the Minister of Health upon various provisions. It is urged that as a general principle it is undesirable to coöpt members on visiting committees who are not directly elected by the ratepayers, and that it is not equitable to give persons who are not directly responsible to the ratepayers, power to coöperate in the direction of the expenditure of the ratepayers' money. As to out-patients, a visiting committee would not be able, it is thought, to contribute to the cost of an out-patient department for mental treatment in a general hospital. Moreover, where, as in many instances, the mental hospital is situated at a considerable distance from large centres of population, it might be desirable to institute an out-patient department away from the mental hospital. The members have been asked by those interested in the management of private institutions and registered hospitals who are subscribers to their Association to urge that no restrictions should be set up under the Bill on the facilities such institutions now have in connexion with the reception, maintenance, and discharge of voluntary boarders. In the opinion of the executive the provisions of the subsection of the Bill dealing with after-care militate against the voluntary principle; they consider it undesirable that after a patient has been discharged from trial he should be in any way associated with the institution. Other minor criticisms are made. Representatives of the Association on the Joint Conciliation Committee have been conferring with the National Asylum Workers' Union for some months past as to the possibility of stabilising, by improving the conditions of service of, the nursing staff in mental hospitals. It is held that probationers should be subject to medical examination before engagement and that they should have reached a certain standard of education—e.g., have passed either the seventh standard at an elementary school, or the Junior Oxford or Cambridge Local Examination, and that the governing authorities be requested to dispense with the services of any probationer nurse who does not make due and diligent efforts to attain the recognised standard of proficiency. The formation of a sports club in every institution to promote recreation among the staff is suggested. It was stated that the Joint Committee have been involved in correspondence with the Ministry of Health as to the constitution and proceedings of a committee set up by the Board of Control, "to consider the nursing service in county and borough mental hospitals and in what direction it can be improved," to which the Joint Committee were not invited to send representatives. As the constitution of the Board of Control's Committee did not commend itself to members of the Joint Committee, it had been unanimously decided not to accept the offer of the Ministry and of the Board of Control to give evidence and submit themselves or their representatives to cross-examination as to their proceedings; but the Joint Committee would continue to furnish the Board, as had been its practice in the past, with copies of the various recommendations which the Joint Committee may from time to time decide upon.

The inaugural meeting of the

National Council for Mental Hygiene

was held at Caxton Hall, Westminster. The chairman of the Council is Sir Courtauld Thomson and the joint hon. secretaries Dr. J. L. Birley and Lieut.-Colonel J. R. Lord. In America a national committee for mental hygiene has been doing valuable work for a number of years, and an international mental hygiene movement has now been launched. The chief purposes of the movement are to work for the conservation of mental health; to promote the study of mental disorders, mental defects, and delinquency in all their forms and relations; to obtain and disseminate reliable data concerning them, to help to raise the standard of care and treatment, and to coördinate existing agencies. The special aims of the British National Council include among others: the improvement of the mental health of the community; the study of the causes underlying congenital and acquired mental disease with a view to its prevention; the securing of a more important position for the study of psychiatry in the medical curriculum and the closer association of psychiatry with general medicine; to further the establishment of special clinics and out-patient departments for the early treatment of mental disorders, and to raise the standard of care and treatment in the public mental hospitals; the study of criminality, dependency, vagrancy, and prostitution, in so far as they are failures of adjustment by reason of mental disease or defect; the study of mental hygiene of child-life in relation to education and parental responsibility. The Council hopes to be the liaison between all societies, associations, and other bodies interested in or concerned with mental hygiene, and as far as it can with advantage coöperate with them. The annual subscription for full members is 1 guinea, for associate members 5s. Donations may be sent to hon. treasurer, Lord Southborough, at Room 55, Windsor House, Victoria-street, London, S.W. 1.

A BIBLIOGRAPHY OF SOCIAL HYGIENE.

A COMPREHENSIVE bibliography of social hygiene, demography, and vital statistics has just been issued by Prof. A. Grotjahn and Dr. phil. F. Kriegl, edited by Dr. Hans Haustein, of Berlin. (Berlin: Richard Schoetz. 1923. Pp. 262. 4s.) The pamphlet contains some thousands of references in various languages to books and papers which appeared in the year 1921, under headings which include the social hygiene of work, of food, of dwelling and clothing for children and young persons, social insurance, and the hygiene of reproduction. The pamphlet will be found a useful work of reference by all who are working in a field to which post-war conditions have given a very urgent importance.

A DETOXICATED PHOTOGRAPHIC DEVELOPER.

METOL, introduced in 1891 as a photographic developer, suffers from the drawback of being seriously irritating to the skin. This is the case with the ordinary commercial form, but it has now been shown by Mr. W. F. A. Herman (*Chemistry and Industry*, May 18th), working in the department of photographic research of the British Dyestuffs Corporation, that pure metol is quite innocuous to the skin. That this was the case has long been suspected, but Mr. Herman has been able to isolate and determine the constitution of the poisonous impurity. By adopting a modification in manufacture, metol free from irritant action can now readily be produced, and Mr. Herman has conferred a boon upon photographers.

A REGISTER BOOK FOR DANGEROUS DRUGS.

Messrs. John Wright and Sons, Ltd., have brought out a register recording the purchase, sale, and stock-in-hand of such dangerous drugs as are scheduled under the Act of 1920. It is intended for the use of medical men, and the preface contains extracts from the regulations issued by the Home Office in Janurary, 1923, including those applicable to (1) all doctors; (2) dispensing doctors. Different coloured pages with thumb-index are provided for records of morphine and salts, diamorphine (heroin) and salts, cocaine and ecgonine and salts, and medicinal opium. The whole is issued in a handy form at 7*s.* 6*d.*

COLONIAL HEALTH REPORTS.

Nyasaland.

THE report for this Protectorate for 1921, for some reason delayed, has now been presented to Parliament. It states that during the year the general health was satisfactory. In the Mlanje district small-pox broke out from time to time, apparently introduced from Portuguese East Africa. In other areas the outbreaks were of a sporadic nature and were easily controlled. Two cases of bubonic plague were reported from the North Nyasa district, but neither case was seen till after death. Although careful investigation was made no further cases were revealed, neither was there any noticeable epizootic disease among the rats with which the district is infested. Barium carbonate was reported to be the most satisfactory of the various rat poisons with which experiments were made during the year. As regards the treatment of venereal disease, experience seems to show that the mental attitude of the native is the same towards this disease as towards others, and that treatment is not usually sought until serious inconvenience is occasioned. Nevertheless, venereal hospitals for the treatment of natives were opened in seven districts during 1921, and the returns show that a beginning has been made in familiarising the people with the opportunities afforded them at these treatment centres. At the venereal hospitals the treatment of yaws is also undertaken, and later on it may be possible to deal more thoroughly with this disease, which is endemic and widely prevalent in the Dedza district. The medical staff was increased during the year, and this

Vacancies.

Births, Marriages, and Deaths.

BIRTHS.

BARRY.—On June 24th, at Hyde Park Barracks, the wife of Captain S. J. Barry, R.A.M.C., of twin sons.

KELLOCK.—On July 4th, at Upper Wimpole-street, W., the wife of the late T. H. Kellock, M.D., M.Ch., F.R.C.S., of a son.

LONGSTAFF.—On July 3rd, at Picket Hill, near Ringwood, the wife of Dr. T. G. Longstaff, of a daughter.

MADGE.—On July 4th, at Brookside, Ashbourne, Derbyshire, the wife of Dr. Quintus Madge, of a son.

MORLEY.—On June 28th, at "Grasmere," Mill Hill, N.W., the wife of Allan Morley, M.B. Lond., of a daughter.

MARRIAGES.

FERRIER—CONEY.—On June 26th, at Studland Church, Swanage, David Ferrier, M.D., of Dunstable-road, Luton, to Adeline Maud Coney, daughter of the late S. W. Coney, Bournemouth.

POSTLETHWAITE—CLAYTON.—On July 3rd, at St. Augustin's Church, Bournemouth, William Barry Postlethwaite, M.B., M.C., to Barbara Clayton, the younger daughter of Dr. and Mrs. A. J. Clayton, of Wimborne-road, Bournemouth.

DEATHS.

BURY.—On July 4th, at Galtee House, Foxley-lane, Purley, Surrey, George Bury, L.R.C.P., M.R.C.S., aged 93.

KIRBY.—On July 3rd, at Bromley Lodge, Bromley, Kent, Dr. Albert Edward Kirby, M.R.C.S. Eng., aged 74.

MURIEL.—On July 3rd, at Glenfield, Whitehaven, George John Muriel, J.P., M.R.C.S. Eng., in his 81st year.

SAYER.—On July 7th, after a prolonged illness, Dr. Ettie Sayer, M.B., B.S., of Ennismore-gardens, W.

STEWART.—On July 3rd, at his home, Yeoveney, Alexandra-road, Watford, suddenly from heart failure, Alexander Brodie Seton Stewart, late of Leeds, Lieut.-Colonel, R.A.M.C.(T.), O.B.E., T.D., Order of St. Sava of Serbia.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

FURTHER NOTES ON SMALL-POX DIAGNOSIS.

BY W. McCONNEL WANKLYN, B.A. CAMB., M.R.C.S. ENG., D.P.H.

To include within a few lines, such as those published in THE LANCET on July 7th, all that should be understood upon this subject is clearly impracticable; the following additional notes may therefore be useful. As the subject is one of the humblest of our professional duties and one which we are endeavouring to get rid of as soon as possible, so also is it one of absolutely fundamental importance for each one of us to tackle until our island is cleared of small-pox beyond any possibility of its return. The laity are keenly alive to the financial risks; when those risks mature they require someone's blood. That is the fact. Many of us may never have a suspected case; some are dead certain to have one or more; and yet others, if unprepared, may thereby be ruined. Wherefore the main point and kernel of interest for us in the matter is not any clinical, academic, or epidemiological feature per se; we have no time for such; but it is this. Can I be reasonably sure of at least challenging any single case of this odious disease that may drift my way? It is with such a query in mind that your readers may be pleased to glance at the notes of the following case, placed at my disposal by one of the various colleagues with whom I have had the pleasure of seeing cases in consultation. An effort is being made to file and reproduce such cases for mutual guidance, and any other notes of the kind will be welcomed. Only those points have been brought out which are likely to be of direct value to the reader, when faced with an awkward case.

An Awkward Case.

The case was that of S. S., a female, aged 6. It was obviously either small-pox or chicken-pox. A count of the spots showed as follows:—Right hand, 5; right forearm, 1; right arm, 10; right foot, 3; right leg, 4; right thigh, 15; left foot, 2; left leg, 4; left thigh, 11; face, 15; front of trunk, 50. This, taken with the superficial and peculiar character of the vesicles, and the absence of initial or constitutional symptoms, was sufficient to establish a diagnosis of chicken-pox. There remained for consideration the rash on the left upper extremity. This was very remarkable. On the left hand were 14 lesions, on the left forearm 4, on the left arm 10. It was the remarkably thick crop on the left hand which led to this case arousing a suspicion of small-pox. But when the facts were gone into this was noted. Previous to her attack of chicken-pox, the child had been suffering from an acutely septic condition of the left hand, for which she had been attending hospital, and it was upon this inflamed area that a numerous and well-developed crop of vesicles had settled.

Herein we come upon a phenomenon which, well known in small-pox, is also present in chicken-pox to a less degree, that is the selection by the rash of irritated surfaces. This much at least comes out as noteworthy, that that factor itself is not pathognomonic of small-pox. I have seen numerous remarkable instances of the same phenomenon in chicken-pox. In one recent case the outline of the garters below the knees in an adult was conspicuously picked out by the rash of small-pox. I have also seen scratch marks picked out by the rash of chicken-pox and other similar sites of irritation, such as those on the skin of ill-tended children.

Four Main Criteria.

It comes to this; that there is no single golden rule, no measuring tape or touchstone by which we can say: This is chicken-pox; that is small-pox. In nine cases out of ten in which the diagnosis rests between chicken-pox and small-pox in an adult, a count of the spots on the upper extremities will correctly point to the truth. In the tenth, it may not so point, as was demonstrated to me by a case only two or three days ago. In children there is more variety in the distribution of the rash of chicken-pox than there is in adults. It more often varies from the accepted type. In all the cases, however, which I can recall, the degree of prostration has been a valuable sign. That is seldom so marked in any case of chicken-pox as it is in small-pox; and it is a remarkable point that where a copious rash due to chicken-pox occurs in a patient, in that patient there is commonly no such degree of prostration as almost invariably occurs in an attack of small-pox of corresponding degree. The four main points which I have consistently found to be most useful in my work are: (1) The distribution of the rash; (2) the degree of prostration; (3) the relative depth of the lesions in the skin; and (4) the maturation of the lesions.

THE LANCET, JULY 21, 1923.

ABSTRACT OF A [*]
Presidential Address
ON
CONSIDERATIONS,
BACTERIOLOGICAL, TOXICOLOGICAL, HÆMATOLOGICAL, AND OTHERS THERETO AKIN, BEARING UPON
THE PSYCHOSES.

Delivered before the Medico-Psychological Association of Great Britain and Ireland on July 10th, 1923,

BY EDWIN GOODALL, C.B.E., M.D., B.S., F.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, CARDIFF MENTAL HOSPITAL.

IN the course of toxic and febrile processes, such as occur in association with typhoid, erysipelas, malaria, pneumonia, influenza, psychoses may arise. Amongst infection-psychoses may be counted insanity of the puerperium; in association with epidemic encephalitis various psychoses develop, a fact of significance in the problems of the pathogenesis of these states. Of peculiar interest is the occurrence of disorders of motility in the course of and after this disease, resembling muscular disorders in katalepsy and katatonia. A recent and valuable addition to the literature of this subject is furnished in an article by Skliar, who has had the unusual experience of seeing mental disturbances in the course of typhus and relapsing fever, prevalent in Russia during the three winters, 1918–1920, inclusive. He also describes five cases of lyssa in which psychotic disturbances occurred. These disturbances also occur as a result of poisoning by alcohol and drugs such as hashish (*Cannabis indica*), lead, and mercury.

THE TOXIC FACTOR.

These disorders of mind, occurring in febrile processes, cannot be due solely to febrile disturbance; the toxic factor must be taken into account. We must persist in the inquiry as to whether certain of the insanities, of everyday occurrence and of unknown origin, and which, prima facie, appear to be of toxic origin are, in fact, ascribable to exogenous or endogenous toxins. To seek experimental evidence which would establish the presence of a toxin as the cause of any variety of mental disorder of unknown origin is a sobering experience, although some people seem to be on terms of familiarity with the toxins of the psychoses, especially as regards the toxins hailing from the bowel.

The evidence furnished by the morbid histology of the brain in the acute and recent psychoses is not in favour of anything approaching a virulent toxæmia, with the possible exception of the condition known as "acute delirium" or "acute delirious mania." Neither clinically (temperature, pulse, respiration) is there definite evidence of a febrile process. Yet, as certain drugs are toxins, able, though not virulent, to produce very definite mental disorder, whilst incapable of producing the bodily disturbance associated with a specific fever, so unknown proteins or their derivatives may function as toxins and cause some of the psychoses, and be responsible for such changes in the brain as the microscope reveals. We must look to biochemical research to help us in the supremely difficult problems of perverted metabolism.

[Dr. Goodall then gave a survey of the results of work in examination of blood, urine, cerebro-spinal fluid, and fæces, and continued as follows:]

The observations recorded are not in favour of a theory of toxæmia, referable to the action of intestinal bacteria, as a cause of the acute mental disorders investigated. But regard must be had to the great labour involved in this kind of work, and therefore the need for many workers, to accumulate results on a large scale. And better methods for detecting and cultivating intestinal organisms may come to our aid. As to this, reference may be made to articles in THE LANCET of July 15th, 1922, p. 127, and the *Journal of Mental Science*, of January, 1923, by Dr. Chalmers Watson, upon the intestinal flora as revealed by the use of a new culture-medium. Ford Robertson in his writings describes several cases of psychoses in which he found an abnormal intestinal flora. Constipation, stercoral retention, toxæmia, acute psychosis—this is the order of events, according to the expounders and the scribes. They can point to the remarkable effects sometimes produced by free purging upon the psychoses, and upon the psychical ebullitions of many persons outside asylums and of the chronic insane in them. But the factors operative, the mode of operation, the links in the chain—in regard to all these, our information is rudimentary. The hardihood which permits of the continued references to an alleged undue occurrence of "indican" (potassium-indoxyl sulphate) in the urine, pointing to auto-intoxication from the bowel, is astonishing, and betrays ignorance of the valuable work done by Stanford (1910–1912) in the Chemical Laboratory at the Cardiff City Mental Hospital.[†] Stanford's findings still hold good. No value attaches to the so-called "indican" evidence of intestinal toxæmia.

Is there satisfactory evidence that disinfectants, such as izal, kerol, dimol, when given by the mouth favourably influence mental disorders of any kind? I am not aware of any. I have personally tried various disinfectants for years. Recently 11 cases of acute and recent mental disorder (melancholia, confusional states, delusional states), and one of chronic hypochondriasis, were treated with dimol in powder form, four of them receiving 8 gr. of the powder and eight 12 gr. of the same, thrice daily (1 part of dimol in 3 parts of the powder), in most cases for several weeks or months. Five other similar cases were given one kerol capsule thrice daily for like prolonged periods. It cannot be said that any dramatic or decisive results were observed in cases which improved or recovered. Nevertheless, in my opinion, such drugs are worth extensive trial for long periods, preferably combined with lavage of the whole large intestine.

In connexion with the subject of bacteria as factors, through their toxins, in determining mental disorders, the observations of Ford Robertson, as recorded in his work on therapeutic immunisation—and in his paper published in the *Journal of Mental Science* of January, 1922, which deals with the special case of dementia præcox—should be studied. Here I can do no more than indicate his main conclusions. According to him, there would appear to be several types of neurotoxic bacterial infection to which the cortical nerve-cells of patients with predisposition to mental disorders show extreme sensitiveness. Three forms of infection are especially prominent—viz., by aerobic and anaerobic diphtheroid bacilli (first and foremost), by pneumococci, by anaerobic streptothrices of the intestines. *Streptococcus pyogenes* and *Streptococcus fæcalis hæmolyticus* also play a part. The bacterial actions are mostly exercised through toxins carried from foci of infection in the alimentary, respiratory, or genito-urinary tracts. Diphtheroid bacilli have frequently been cultivated from the blood in cases of acute toxic insanity and general paralysis. The pathogenic action of these organisms is demonstrated by focal reactions; by hypersensitiveness to autogenous vaccines, by the success of therapeutic immunisation in relieving symptoms, and by the comparative paucity or complete disappearance of the bacteria upon repetition of the bacteriological examination when the patient had recovered partially or completely.

---

[*] This address will appear in full in the Journal of Mental Science, October, 1923.

[†] Published in the Zeitschr. f. physiologische Chemie (Bände 87, H. 3, and 88, H. 1).

fact, combined with other circumstances, enabled medical aid to be extended to districts hitherto unprovided for. Indian subassistant surgeons are stationed at posts of secondary importance, and, in addition, rural dispensaries are being opened in the more populous centres in each district under the charge of natives trained for the purpose and visited periodically by medical officers or subassistant surgeons. It is hoped that such schemes for increasing the medical facilities afforded to natives in remote districts will be further developed and extended in other directions as soon as the finances of the Protectorate permit. It is understood that the drug Bayer "205," which is being experimented with in the Northern Rhodesia, is a decided advance on any treatment which has hitherto been employed in the cure of trypanosomiasis. The medical entomologist is studying the preventive side of this disease. As regards sickness amongst the European population, 366 cases were treated during the year by the medical department, and there were 12 deaths. Malaria was responsible for 28 per cent. of the cases dealt with, and, of course, many cases of malaria are self-treated and do not come under official cognisance. Gastro-intestinal disorders, respiratory complaints, and dysentery made up the bulk of the other cases treated. There were 14 cases of blackwater fever, resulting in two deaths. European and native hospitals are maintained by Government at Blantyre, Zomba, and Fort Johnston, and additional native hospitals at Port Herald, Mlanje, and Karonga; others are in course of erection or are to be built later. The various missions established in the Protectorate continue to do a considerable amount of medical work. According to the census taken in April, 1921, the population of Nyasaland was 1486 Europeans, 563 Asiatics, and 1,199,934 natives (558,138 males and 641,796 females). The climate in its essential features is similar to that of the rest of Eastern Africa within the tropics. As a large proportion of the Protectorate lies at an altitude of 3000 feet or more the heat is not generally excessive.

Falkland Islands.

Mr. H. Henniker-Heaton, colonial secretary, in his report for 1921, states that according to the census taken in April of that year the total population of the colony, exclusive of crews of ships in harbour in Stanley, numbered 2087 (males 1182, and females 905). South Georgia, the only part of the dependencies which is permanently habitable, had at the same time a population of 1337 (of whom only three were females), mainly engaged in whaling, no fewer than 998 being set down as natives of Sweden or Norway. The Falkland Islands proper, consisting of East Falkland and West Falkland, are entirely devoted to sheep-farming; in general appearance they are treeless, bleak, and inhospitable, resembling closely parts of the north-west coast of Scotland and the Shetland Islands. The inhabitants are almost exclusively people of pure British descent; they are hardworking, thrifty, and peaceable. The climate is generally healthy, and there is neither endemic nor epidemic sickness in the country. In the dependencies, also, there is very little sickness, even colds being of rare occurrence, though some unhealthiness is caused by the absence of fresh provisions.

INSULIN "A.B." BRAND.

THE British Drug Houses, Ltd., announce that increased output of insulin "A.B." brand has enabled them to effect a reduction in its price from 2*s.* 6*d.* to 1*s.* 9*d.* per dose. Bottles containing 5 c.cm. (100 units or 10 doses) are now priced at 17*s.* 6*d.* per bottle; bottles containing 10 c.cm. (200 units or 20 doses) at 35*s.* per bottle. These prices have been arranged in agreement with the Medical Research Council and are effective as from July 12th, 1923. Supplies of insulin "A.B." brand now available are sufficient to meet all demands.

GAS CYLINDERS IN HOT WEATHER: SAFETY FIRST.

THE explosion of a gas cylinder in the operating theatre of a London hospital early this week—most fortunately without harm to life or limb—is a reminder of the fact that respect must be paid to the laws of expansion of liquids and gases, although almost complete immunity from such accidents in medical practice has led to their being overlooked. Oxygen and hydrogen being non-liquifiable at ordinary temperatures expand in orderly fashion, and although it is undesirable to expose such cylinders to direct sunshine the risk is not very great. But in the case of CO_2 and N_2O, which are present in liquid form in the cylinders, the coefficient of expansion is much greater than that of gases; hence, to guard against risk, these cylinders are only partially filled with liquid. The manufacturers enjoin strict precautions on their own staff. The British Oxygen Company, Ltd., for instance, issue a special *summer notice* to the effect that during hot weather full cylinders must not be left exposed to the sun in any part of the factory, and that naked cylinders conveyed in open vans, trucks, or by hand, must be covered.

A MONOGRAPH ON DEATH.

Dr. Eugen Holländer has brought out a German edition of Dr. F. Parkes Weber's well-known monograph on Death, under the title of Des Todes Bild. (Berlin: F. Fontane and Co. 1923. Pp. 274.) In a preface, addressed to the author, whose acquaintance he made shortly before the war "in the beautiful home of the Royal Society of Medicine in London," he speaks of medical men as having been in the past leaders and heralds of peace in all parts of the world and destined to play a part in putting on the lines again the derailed wheels of culture. Death, he says, has lost its terrors for hundreds of thousands of German families, and the problems of life and death have come nearer home to many who were not in the ordinary way philosophers; and Dr. Holländer instances the enormous increase in the German book trade as proof of the hunger after mental food and as a salutary counterpoise to mysticism and the resort to priestcraft. Apart from the preface, he has not added to Dr. Weber's book (which has on economical grounds been much abbreviated) material of his own, "in view of the completeness of the original." His prefatory remarks conclude with a note on euthanasia, or the teaching of the right manner of dying, as a lost art, which has, more than any other medical science, lapsed into forgetfulness. Alongside the ideal of a beautiful life stands as equally to be desired a beautiful death.

Medical Diary.

ABSTRACT OF A[*]

Presidential Address

ON

CONSIDERATIONS,

BACTERIOLOGICAL, TOXICOLOGICAL, HÆMATOLOGICAL,

AND OTHERS THERETO AKIN, BEARING UPON

THE PSYCHOSES.

Delivered before the Medico-Psychological Association of Great Britain and Ireland on July 10th, 1923.

BY EDWIN GOODALL, C.B.E., M.D., B.S.,
F.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, CARDIFF MENTAL HOSPITAL.

IN the course of toxic and febrile processes, such as occur in association with typhoid, erysipelas, malaria, pneumonia, influenza, psychoses may arise. Amongst infection-psychoses may be counted insanity of the puerperium; in association with epidemic encephalitis various psychoses develop, a fact of significance in the problems of the pathogenesis of these states. Of peculiar interest is the occurrence of disorders of motility in the course of and after this disease, resembling muscular disorders in katalepsy and katatonia. A recent and valuable addition to the literature of this subject is furnished in an article by Skliar, who has had the unusual experience of seeing mental disturbances in the course of typhus and relapsing fever, prevalent in Russia during the three winters, 1918–1920, inclusive. He also describes five cases of lyssa in which psychotic disturbances occurred. These disturbances also occur as a result of poisoning by alcohol and drugs such as hashish (*Cannabis indica*), lead, and mercury.

THE TOXIC FACTOR.

These disorders of mind, occurring in febrile processes, cannot be due solely to febrile disturbance; the toxic factor must be taken into account. We must persist in the inquiry as to whether certain of the insanities, of everyday occurrence and of unknown origin, and which, prima facie, appear to be of toxic origin are, in fact, ascribable to exogenous or endogenous toxins. To seek experimental evidence which would establish the presence of a toxin as the cause of any variety of mental disorder of unknown origin is a sobering experience, although some people seem to be on terms of familiarity with the toxins of the psychoses, especially as regards the toxins hailing from the bowel.

The evidence furnished by the morbid histology of the brain in the acute and recent psychoses is not in favour of anything approaching a virulent toxæmia, with the possible exception of the condition known as "acute delirium" or "acute delirious mania." Neither clinically (temperature, pulse, respiration) is there definite evidence of a febrile process. Yet, as certain drugs are toxins, able, though not virulent, to produce very definite mental disorder, whilst incapable of producing the bodily disturbance associated with a specific fever, so unknown proteins or their derivatives may function as toxins and cause some of the psychoses, and be responsible for such changes in the brain as the microscope reveals. We must look to biochemical research to help us in the supremely difficult problems of perverted metabolism.

[Dr. Goodall then gave a survey of the results of work in examination of blood, urine, cerebro-spinal fluid, and fæces, and continued as follows:]

The observations recorded are not in favour of a theory of toxæmia, referable to the action of intestinal bacteria, as a cause of the acute mental disorders investigated. But regard must be had to the great labour involved in this kind of work, and therefore the need for many workers, to accumulate results on a large scale. And better methods for detecting and cultivating intestinal organisms may come to our aid. As to this, reference may be made to articles in THE LANCET of July 15th, 1922, p. 127, and the *Journal of Mental Science*, of January, 1923, by Dr. Chalmers Watson, upon the intestinal flora as revealed by the use of a new culture-medium. Ford Robertson in his writings describes several cases of psychoses in which he found an abnormal intestinal flora. Constipation, stercoral retention, toxæmia, acute psychosis—this is the order of events, according to the expounders and the scribes. They can point to the remarkable effects sometimes produced by free purging upon the psychoses, and upon the psychical ebullitions of many persons outside asylums and of the chronic insane in them. But the factors operative, the mode of operation, the links in the chain—in regard to all these, our information is rudimentary. The hardihood which permits of the continued references to an alleged undue occurrence of "indican" (potassium-indoxyl sulphate) in the urine, pointing to auto-intoxication from the bowel, is astonishing, and betrays ignorance of the valuable work done by Stanford (1910–1912) in the Chemical Laboratory at the Cardiff City Mental Hospital.[†] Stanford's findings still hold good. No value attaches to the so-called "indican" evidence of intestinal toxæmia.

Is there satisfactory evidence that disinfectants, such as izal, kerol, dimol, when given by the mouth favourably influence mental disorders of any kind? I am not aware of any. Five other similar cases were given one kerol capsule thrice daily for like prolonged periods. It cannot be said that any dramatic or decisive results were observed in cases which improved or recovered. Nevertheless, in my opinion, such drugs are worth extensive trial for long periods, preferably combined with lavage of the whole large intestine.

In connexion with the subject of bacteria as factors, through their toxins, in determining mental disorders, the observations of Ford Robertson, as recorded in his work on therapeutic immunisation—and in his paper published in the *Journal of Mental Science* of January, 1922, which deals with the special case of dementia præcox—should be studied. Here I can do no more than indicate his main conclusions. According to him, there would appear to be several types of neurotoxic bacterial infection to which the cortical nerve-cells of patients with predisposition to mental disorders show extreme sensitiveness. Three forms of infection are especially prominent—viz., by aerobic and anaerobic diphtheroid bacilli (first and foremost), by pneumococci, by anaerobic streptothrices of the intestines. *Streptococcus pyogenes* and *Streptococcus fæcalis hæmolyticus* also play a part. The bacterial actions are mostly exercised through toxins carried from foci of infection in the alimentary, respiratory, or genito-urinary tracts. Diphtheroid bacilli have frequently been cultivated from the blood in cases of acute toxic insanity and general paralysis. The pathogenic action of these organisms is demonstrated by focal reactions, by hypersensitiveness to autogenous vaccines, by the success of therapeutic immunisation in relieving symptoms, and by the comparative paucity or complete disappearance of the bacteria upon repetition of the bacteriological examination when the patient had recovered partially or completely.

---

[*] This address will appear in full in the Journal of Mental Science, October, 1923.

[†] Published in the Zeitschr. f. physiologische Chemie (Bände 87, H. 3, and 88, H. 1).

Although, as far as my reading goes, very little notice has been taken of Ford Robertson's work in either English or foreign literature, my opinion is that this work cannot be ignored, and should be repeated on the lines indicated by him. This would involve bacteriological examination by aerobic and anaerobic methods of the naso-pharynx, of the stools, and of the urine, using, amongst other media, the hæmoglobin-agar introduced by Ford Robertson and Orr, a medium which is very rarely employed. The extensive work of Cotton and his associates on focal infection in mental disorders is an additional argument for the cultivation of this field of research. Amongst sites of focal infection are the teeth, tonsils, naso-pharynx, gastro-intestinal tract, and genito-urinary tract. The improvement in mental disorders recorded as following removal of sources of infection, and vaccination with organisms found, is clinical evidence, at any rate, of toxæmia.

Time will not allow me to deal further with this portion of my theme. I content myself with drawing attention to an observation recorded by Scholberg and myself. In the wash-out (with normal saline) of the fasting stomach in cases of insanity at adolescence (many of these of the dementia præcox group) we found pus cells in a very large proportion—about 60 out of 68 cases. I understand from Dr. H. A. Scholberg, who is pathologist to the Cardiff Royal Infirmary and to the Cardiff Mental Hospital, that these are not found, in his experience, amongst the usual infirmary patients, apart from instances of lesions of the gastric mucosa. This would appear to dispose of the decayed-teeth hypothesis. Possibly some focus in the naso-pharynx was the original source of these pus cells. The matter is at present obscure.

TOXICITY OF BLOOD, CEREBRO-SPINAL FLUID, AND URINE IN MENTAL DISORDERS.

The following summary of information bearing upon the question of the toxicity of the blood, cerebro-spinal fluid, and urine of cases of mental disorder may be recorded. In the course of experimental work done personally or in conjunction with co-workers (Drs. Scholberg and Cameron), a very large number of rabbits and fowls have been injected with blood serum, or blood corpuscles, or the stroma of such, from all the main clinical varieties of insanity, including cases of violent mania, profound melancholia, dementia præcox in its various forms, epilepsy, and dementia paralytica. The losses of weight and the deaths resulting from injections with serum and blood corpuscles were fully equalled by those observed in control animals injected with the like from healthy blood; so that effects a priori ascribable to a toxic cause were, in fact, not due to such. In the case of injection with the stroma of r.b.c., whilst heavy death- and loss of weight-rates obtained in animals injected from the cases of acute insanity, there were no losses and no deaths in the case of those injected with control blood. On this point further experience is necessary.

The small proportion of deaths in fowls compared with rabbits (serum used in both) argues greater resistance in the former. Contrary to what has been affirmed, we did not find the fowl a better precipitin-producer than the rabbit.

Meyer's experiments upon toxicity of the blood of epileptics show the need for further research on the point, and preferably with animals higher in the scale than those used by him. Ten of 11 guinea-pigs injected intraperitoneally with 10–15 c.cm. of defibrinated blood from normal persons showed no symptoms. The eleventh died after convulsions. Of ten guinea-pigs injected with blood removed during an epileptic seizure, nine had typical tonic clonic convulsions in from 1 to 5 hours after injection. Blood removed in the interval between fits affected the animals according to the time elapsing since the last seizure and to the severity of the disease. Preda and Popea (cited by Barbé) state that the serum of epileptics is not toxic for man. Cuneo has recently described a research by which he has obtained from the blood serum of epileptics albumoses, which, injected intravenously into dogs, produce the characteristic phenomena of convulsive seizure. He ascribes epileptic seizures to the action of these albumoses. His paper describes the mode of formation of these substances in the blood of epileptics. Loewe found that the dried insoluble portion of the adialysable substance of urine is, in the katatonic type of dementia præcox, in dementia paralytica (after seizures), and in delirium tremens, highly toxic. In epilepsy it is, in addition, capable of producing seizures very like epileptic ones, injected intravenously. Similar adialysate from the urine of normal persons is not toxic. I consider that further work requires to be done on this subject of toxicity of the body fluids, subdural and intraperitoneal injections being employed.

CHANGES IN THE LEUCOCYTE COUNT.

The existence of leucocytosis in toxic conditions has naturally led various workers to seek for evidence of toxicity in the psychoses as shown by quantitative and qualitative changes in the leucocyte count. I would summarise present knowledge in regard to the leucocyte count in those mental disorders in which it has principally, if not wholly, been investigated as follows:—

Insanity of Adolescence (Dementia Præcox).—In the earlier phases there is a moderate increase in the total white-cell count, with relative increase of the neutrophiles. Thereafter, in marked exacerbations of the morbid processes, these increases are more pronounced. The progress towards dementia is characterised by a relative lymphocytosis, with a low total count. There is not sufficient evidence of differences—quantitative or qualitative—in the cell counts in the different forms of dementia præcox.

Insanity with Epilepsy.—There is a considerable degree of accord between observers, the results showing leucocytosis and polynucleosis with *hypo-eosinophilia* in connexion with seizures, *uncharacteristic conditions* obtaining in the intervals.

Mania—Melancholia.—A high total count, with relative neutrophile increase at the onset; these subside as the disease progresses; perhaps a second minor increase accompanies symptoms of recovery. The persistence of this, with a normal percentage of neutrophiles after recovery, is a favourable sign (Bruce). A fall in the neutrophile percentage without mental improvement is an unfavourable sign (McDowall). In unfavourable cases the counts are variable, and lymphocytosis becomes apparent with the lapse of time. In subacute and chronic conditions, lymphocytes predominate (Klippel and Lhermitte).

More evidence is required as to subacute and long-lasting cases, and as to the count at the stage when it is apparent that recovery is to take place. Whilst statements as to isolated occasional white-cell counts in acute mania and melancholia are pretty frequent, it is remarkable how few have conducted inquiry in these conditions over long periods. This criticism, as I have indicated, applies to the cell counts in the psychoses generally, but one would have thought an exception would have been made in cases of the particular kind just discussed, conveying strongly, as they do, the impression of toxic pathogenesis. In puerperal insanity the leucocyte count resembles that of acute mania.

States of Acute Confusion.—Leucocytosis: polynuclear increase (both moderate); hypo-eosinophilia; these pass away with decline of the illness and recovery.

Dementia Paralytica.—In the first stage moderate leucocytosis with relative neutrophile increase; in the early second stage, these conditions continue, but in the later second and in the third stages, whilst the moderate leucocytosis is maintained, the lymphocytes, small and large, are relatively increased at the expense of the neutrophiles. A relative polynucleosis, with frequently only a slight increase in the total count, accompanies the febrile attacks of the later stages, also the paralytic seizures. In states of remission and of marked quiescence there is a relative lymphocytosis, replaced by polynucleosis on the occurrence of exacerbations. The evidence furnished by the leucocyte count in the psychoses dealt with is in favour of toxæmia, not a grave form of it.

The observations of Pfeiffer and de Crinis, published in 1913, relative to the increase of anti-proteolytic substances (as brought out by the *antitrypsin test*) in the serum of cases of the "organic" as distinguished from the "functional" and constitutional psychoses, are borne out by Bolten's observations, made in 1918, but still require confirmation. In case of confirmation it remains that the nature of the antitryptic substances (so-called "defence-ferments") is unknown. More work appears to have been done on the continent with Abderhalden's method, which is declared to demonstrate the presence in the serum of protective ferments against break-down products of parenteral protein—e.g., from the cerebral cortex, genital glands, &c. These ferments are stated to be present in cases of dementia paralytica and dementia præcox, but not in "functional" and "constitutional" psychoses—e.g., manic-depressive, paranoia. These findings are still in dispute. The latest work with which I am acquainted is that of Ewald, to which I would refer those interested.

EFFECTS OF INTERCURRENT MALADIES ON MENTAL DISORDER.

Efforts to ameliorate or cure mental disorder prompted by the observed effects in these directions of intercurrent maladies are familiar to us all. They are sometimes dramatic. Probably typhoid, erysipelas, and malaria are most efficacious, but pneumonia is also potent, as is also a septic infection. A febrile reaction is not an essential factor in the production of improvement or cure of the insanity. I should say that mania, melancholia, confusional, and stuporose states are chiefly benefited by intercurrent disease. Intercurrent disease may bring about remarkable remissions in dementia paralytica; remissions of extraordinary length are recorded.

The attempt to imitate the effect of intercurrent disorders by the subcutaneous injection of nucleinic acid, or sodium nucleinate, dates back to about 1909. Sodium nucleinate was probably chosen because of its ability to produce a decided leucocytosis. Recently "phlogetan," a substance stated to be a derivative of albuminoid bodies containing nucleo-protein from cell-contents, has been employed by Fischer and others as being more intensive in action than nuclein. The work of these authors shows that a leucocytosis results from these injections, and, in my experience, with sodium nucleinate the injection results in leucocytosis with a considerable proportionate rise in the neutrophile count. The pulse-rate was increased in my observations, but rise in temperature was not marked. Having regard to the results recorded by the above workers in cases of dementia præcox, and by others in psychoses with indications of a toxic origin, one would have thought that this treatment, associated with the use of colloidal metals, which also produce leucocytosis, with increase in the neutrophile percentage, would have been more persistently and extensively tried.

From a paper published by Gerstmann in 1922, it appears that the Vienna School, under Prof. Wagner-Jauregg, who instituted the treatment, is still systematically carrying out the treatment of dementia paralytica by the subcutaneous injection (accompanied or not by scarification) of the parasite of tertian ague into the patient. After 8 to 12 pronounced malarial attacks, treatment by quinine and neo-salvarsan is instituted. I would refer you to the article which I cite for an account of the successful results (in respect of production of remissions) achieved; also one by Wagner-Jauregg in the *Journal of Nervous and Mental Disease* of May, 1922, and one by Pilcz in THE LANCET of Jan. 6th, 1923, p. 19. This therapeutic measure is also favourably reported upon by Gans. This treatment of dementia paralytica, with a view to production of remission, by the inoculation of patients with blood taken from patients shortly before a malarial attack, or blood of mice which had been inoculated from a case of relapsing fever—the mental cases being inoculated either subcutaneously or intravenously—is also being carried out at the Hamburg Psychiatric Clinic and the results up to date (1922) are fully reported upon by Kirschbaum. I would suggest that a reaction with production of anti-substances to the spirochæte of relapsing fever, or even to the *Plasmodium malariæ* (a protozoon), might theoretically be expected to be more efficacious in dementia paralytica than any reaction as a result of inoculation of bacilli, since the above organisms are biologically more closely related to the spirochæte of syphilis. Stimulation of the defences by inoculation with the virus of syphilis would seem to be a more rational procedure than the above. According to Scharnke (Marburg) cautious experiments in this direction have long been in progress, though I have not come across any accounts of the results.

The beneficial results of intercurrent maladies, and of the therapeutic measures referred to above, upon the insanities may be examples of non-specific protein therapy. We are far from understanding the rationale of this treatment, and it is unprofitable to discuss the theories advanced on the subject.

It would appear worth while to pursue the inquiry as to the effect of non-specific parenteral protein therapy in mental disorders suggestive of a toxic origin. Any experience available is worth brief record, even though negative; in the latter case, time will be saved to intending workers. I have used a 1 per cent. solution of Armour's peptone, in doses up to 1 c.cm., intravenously. This was sterilised by filtration through a porcelain candle. With it I obtained no physical or psychical evidence of reaction. I would make the suggestion that Witte's peptone, either added to the above or alone, might be tried. The risk of anaphylaxis cannot be dismissed with intravenous injections, and it is doubtful whether they are superior to intramuscular ones.

PRODUCTION AND SPECIFICITY OF ANTIBODIES.

Production of antibodies by inoculation of animals with the sera, red blood corpuscles, or stroma of same, of cases of mental disorder: specificity or otherwise of such. In 1913 I inquired into the point as to whether the blood-serum of the insane produces specific precipitin when inoculated intravenously into rabbits. The results were estimated by naked-eye observations. From these it was gathered that a given anti-serum produced the same amount of precipitate, whether put up against the actual serum by which it was produced, the serum of patients suffering from the same mental disorder, or the serum of patients suffering from other kinds of insanity. There was no specificity of reaction. There is room for further work in this direction, an agglutinoscope, or even a low power of the microscope, being employed in reading the results. In 1921–1922 further work on the same subject was done by Dr. Scholberg, Dr. Cameron (of Cardiff), and myself. Red blood corpuscles, or the stroma of such, were used as antigens, in addition to serum. The same lack of specificity was noted. Interesting is our failure to produce antibodies (as tested against c.s.f. of G.P. and non-G.P.) by the injection into rabbits of large amounts of cerebro-spinal fluid from G.P.'s, and choroid-plexus emulsion, from cases of dementia paralytica, and control-plexuses from other kinds of disease. In conjunction with Scholberg and Cameron I have entered into the question of production of specific anti-substances by the injection into animals of the serum, whole red blood corpuscles, or stroma of such, from cases *recently received* of acute mental disorder. The argument was that if these acute and recent states had been produced by an unknown toxin, such would have produced antibodies in the patient's blood, which, in turn, might be expected to evoke anti-substances when injected into animals. It was found, however, that such anti-substances as were produced were not specific, but reacted as much with a control's blood as with that of the patient from whom the injections were made. The antibodies looked for were precipitin, hæmolysin, and hæmagglutinin; there is room for further research as to complement fixation.

An inquiry was made by us as to whether the psychoses, or any of them, could be classified in the four blood-groups of Moss, who placed human beings in four groups, according to the ability of their serum to cause agglutination, and of their corpuscles to be agglutinated. According to Moss, agglutinins appear with approximately the same relative frequency in health and various diseases, and have no diagnostic significance. Therefore, it was not surprising that we found, having examined 262 cases, that instances of various kinds of mental disorder occurred in each and any of the groups, and that, therefore, the psychoses are not classifiable in these groups.

It still remained of interest to inquire—irrespective of the question of insanity—whether the precipitin, hæmolysin, or hæmagglutinin, produced in the serum of rabbits or fowls by inoculation of serum, or blood corpuscles, or their stroma from cases in a given group, gave a greater reaction with antigens (serum or r.b.c.) of that group than with those of another group. In respect of the two groups (1 and 4) dealt with, a large number of tests showed that there was *no group-specificity*. Fowls were injected intravenously and intraperitoneally, in the first case with repeated doses, in the latter with one large dose (20 c.cm.), only serum being injected. Rabbits were injected intravenously with repeated doses of all the antigens in question. An interesting point, meriting further investigation, emerged in the course of this experimental work; it was found that the anti-serum against stroma of red blood corpuscles produced, with the red blood corpuscles tested, agglutination much more frequently, or more strongly, than anti-serum obtained by injection of whole red blood corpuscles.

BRONCHOMONILIASIS.

BY TH. JOEKES, M.B. LEIDEN, M.R.C.S.,
LATE SENIOR DEMONSTRATOR OF PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL;

AND

R. H. SIMPSON, M.D., M.R.C.P. LOND., D.P.H. OXF.,
ASSISTANT PHYSICIAN, EAST LONDON HOSPITAL; LATE CHIEF ASSISTANT TO A MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.

ONLY within recent years has there been any general recognition of the frequency with which mycotic infections of the respiratory tract occur. In 1910 Castellani[1] drew attention to the part played by fungi of the genus Monilia, and published an account of 22 cases occurring in Ceylon. Since that time numerous other instances have been recorded, notably in Egypt,[2] Italy, and South America.[3] Cases have also been found in Siam,[4] China,[5] South Africa,[6] France, and elsewhere. In general it may be said that the maximum incidence occurs in climates which are both hot and moist. Fungi of the Monilia group are members of the family Oösporaceæ, to which class belong those of the closely allied genus Oidium. Outside the body they are widely distributed, and may be found more especially on fruit and on dead leaves and wood. In the sputum they appear as round or oval Gram-positive, yeast-like bodies, sometimes showing a double contour (Fig. 1). Fragments of mycelium may also be found, often in bacillary or coccoid forms. Not infrequently tiny white particles, representing masses of growth, may be visible to the naked eye.

Although cultures may be obtained on ordinary media, a more copious growth occurs in those which are slightly acid in reaction and contain a percentage of some sugar—e.g., glucose or maltose. Growth occurs readily at room temperature, but in some cases is more rapid at 37° C. On solid media (Fig. 3) the cultures are usually of a creamy-white colour; later, a brownish pigmentation often appears. They are composed of the yeast-like bodies only. In liquid media, bacillary and filamentous forms may be found (Fig. 2). Numerous species have now been isolated. For their identification, use has been made of their powers to ferment various "sugars" with the production of gas. Castellani has demonstrated that these powers are remarkably constant in freshly isolated strains, and on this basis has evolved a comprehensive classification.[7]

Infection in Man.

In man direct infection from case to case may possibly occur. More commonly, however, bronchomoniliasis results from the inhalation of contaminated particles. The relatively high incidence among tea-tasters in Ceylon confirms this view, and gives some indication of the importance of the occupational factor. The further possibility that pulmonary infection may occur by spread from a cutaneous source is suggested by the researches of Wade,[8] who succeeded in producing chronic lesions with cavitation in the lungs of a monkey after subcutaneous injection of a broth culture of *Blastomyces dermatitidis.* It is noteworthy that in cases of primary infection of the respiratory tract the mouth and pharynx usually escape. Secondary infection from this source may, however, occur in debilitated persons. Instances of mixed infection are not uncommon, notably with the tubercle bacillus or, in tropical countries, with *Spirochæta bronchialis* or *Paragonimus westermanni.*

Clinical Features.

Clinically, all grades of severity are to be met with. In the milder cases the general health is not seriously impaired, and there is very little fever. Physical examination reveals signs of bronchitis, or perhaps of broncho-pneumonia. In the more severe instances wasting is marked, and may be accompanied by all the signs and symptoms usually associated with pulmonary tuberculosis. Intermediate types are not uncommon and may run a prolonged course with one or more relapses.

Post-Mortem Findings.

As the majority of cases recover, post-mortem records are scanty. It would appear, however, that the initial lesion is a bronchitis, from which extension may occur with the production of an acute or chronic broncho-pneumonic consolidation. In some instances circumscribed tubercles may be found. Mendelson,[4] describing a chronic case in which death occurred from intercurrent disease, states that the lungs were firm and contained numerous white nodules resembling those found in tuberculosis—except for the fact that they showed no sign of breaking down. Boggs and Pincoffs[9] record a further case, complicated by the presence of carcinoma mammæ in which abscesses above and below the left clavicle communicated through numerous small openings in the thoracic wall with a localised empyema beneath it. The left lung was densely adherent to the chest wall. Its upper lobe was solid, firm, and grey. In the lower lobe were scattered areas of consolidation, especially at the apex. The bronchi showed evidence of inflammation, and the hilus glands were enlarged and contained translucent areas. A third case, complicated by pulmonary tuberculosis, is reported by Macfie and Ingram.[10] A pyo-pneumothorax was present on the left side, and contained thick creamy pus. Numerous tubercles were present in both lungs, many of them caseating. Tubercle bacilli were demonstrated in the lungs; in the pleura both tubercle bacilli and *Monilia tropicalis* were present. These two organisms had been found in the sputum in large numbers during life.

Animal Experiments.

Various attempts have been made to induce direct infection of the respiratory passages of animals. In 1912 Castellani[11] succeeded in producing broncho-pneumonia in a guinea-pig as the result of repeated insufflations of tea-dust. In 1915 Boggs and Pincoffs[9] obtained lesions in the lungs and other viscera of rabbits as the result of injections of pure cultures of Monilia into the trachea. Insufflation experiments carried out on monkeys by Chalmers and MacDonald failed to give clinical results.[24] The subcutaneous route has also been utilised. Using pus and sputum, Farah[25] obtained negative results, and with broth cultures only succeeded in producing a local induration in rabbits. Intraperitoneal injection, however, resulted in a brisk general reaction followed by recovery; intravenous administration invariably produced disseminated lesions, notably in the lungs and kidneys, and resulted in death within a few days. This last observation has been confirmed by many observers.

With regard to these experiments, which are reported to have given negative results, it is of interest to note that Mendelson[12] succeeded in finding areas of consolidation and small non-caseating nodules, together with enlargement of the bronchial glands in guinea pigs, which failed to show any clinical disturbance, even after the lapse of several weeks after inoculation.

It seems to be fully established that lesions produced by various species of Monilia are indistinguishable from each other. Using cultures of *Monilia pinoyi* isolated from Case 2, we have obtained the following results in rabbits:—

1. As the result of intravenous injection of 5 c.cm. of a moderately turbid emulsion, one rabbit died after three days; a second, obviously ill and rapidly losing weight, was killed on the eighth day. In both, numerous miliary lesions resembling tubercles were found in the organs, especially in the lungs, liver, spleen, and kidney (Fig. 4). Cultures made from these yielded a pure growth of *Monilia pinoyi*. Sections showed the presence in them of both oval and filamentous forms of Monilia in large numbers. In all the organs the perivascular distribution of the lesions was very noticeable. In the lung there was also evidence of peribronchial infiltration.

2. Intratracheal injection of similar emulsions produced no gross clinical symptoms apart from a slight cough. This rabbit was killed after eight months. The only macroscopic lesions found were small scattered patches of consolidation in the lungs. In sections, apart from the consolidation, marked peribronchial infiltration could be seen (Fig. 5), and small tubercles composed chiefly of endothelial and plasma cells and having hyaline non-caseating centres.

In the consolidated areas the arteries showed very obvious thickening.

Cases.

The following cases may be of interest in that their nature was discovered in the course of routine investigation of patients in this country. The first occurred in the private practice of one of us (Th. J.), the others among patients admitted to St. Bartholomew's Hospital.

CASE 1.—A married woman came under the observation of one of us (Th. J.) in April, 1920, suffering from an illness which presented all the clinical features of pulmonary tuberculosis. For two years she had been troubled by cough and the expectoration of muco-purulent material, at times blood-stained. Fever was present, accompanied by sleep sweats and progressive emaciation, and weakness which had for some time confined her to bed. Well-marked signs of consolidation were present at the apices of the lungs. A curious feature of the case was the fact that, although the sputum had been examined on no fewer than 17 occasions tubercle bacilli had never been found. A fresh specimen was obtained, and in it were seen numbers of tiny white masses, which proved to consist of yeast-like bodies of which large numbers were visible in films. No tubercle bacilli were seen. Cultures from this and from subsequent specimens on Sabouraud's medium yielded a profuse growth of Monilia (untyped).

As a result of these findings increasing doses of potassium iodide were given. The effect was most marked. The general condition improved rapidly, and within two months the patient was able to get up and to walk about. She was seen again at the end of a year, and appeared to be in perfect health.

This case illustrates how chronic may be the course of the infection, and how readily the condition may be confounded with that of pulmonary tuberculosis.

CASE 2.—A man of 32 was admitted under the care of Dr. H. H. Tooth in December, 1920. He had for the past two years been engaged in unpacking syphons sent from Austria, in dirty and dusty straw. Both he himself and his fellow workers frequently suffered from pustules on the exposed parts of the arms and face. About ten days before admission he developed a slight cough with scanty expectoration. This gradually increased in severity and became associated with fever and malaise. Herpes labialis was present on the left side. The fauces were red and injected, and there were signs of consolidation at the base of the right lung—signs which did not wholly disappear until a month later. The spleen was just palpable. The temperature began to fall on the eleventh day after the onset of acute symptoms, and reached normal by lysis. Thenceforward convalescence was *rapid*, *interrupted* only by an acute follicular tonsillitis in the fourth week.

The sputum, at first scanty, later became more copious; it was muco-purulent and free from blood. Numerous small white specks were visible in it. In films were seen numbers of oval Gram-positive bodies, and numerous bacillary and filamentous forms. Cultures on Sabouraud's medium yielded a copious growth of *Monilia pinoyi*.

When last seen, some six weeks after admission, the patient was in good health and free from cough. Monilia was still present in the sputum, though in smaller amount than previously.

CASE 3.—A girl of 16, a cigarette packer, came under Dr. Tooth's observation in March, 1921, with signs of broncho-pneumonia at the base of the left lung, which persisted for three weeks. The onset was sudden, accompanied by cough and by a considerable rise in temperature, which fell to normal by lysis on the sixth day. As in the previous case, convalescence was interrupted by an acute tonsillitis with expected to evoke anti-substances when injected into animals. It was found, however, that such anti-substances as were produced were not specific, but reacted as much with a control's blood as with that of the patient from whom the injections were made. The antibodies looked for were precipitin, hæmolysin, and hæmagglutinin; there is room for further research as to complement fixation.

An inquiry was made by us as to whether the psychoses, or any of them, could be classified in the four blood-groups of Moss, who placed human beings in four groups, according to the ability of their serum to cause agglutination, and of their corpuscles to be agglutinated. According to Moss, agglutinins appear with approximately the same relative frequency in health and various diseases, and have no diagnostic significance. Therefore, it was not surprising that we found, having examined 262 cases, that instances of various kinds of mental disorder occurred in each and any of the groups, and that, therefore, the psychoses are not classifiable in these groups.

It still remained of interest to inquire—irrespective of the question of insanity—whether the precipitin, hæmolysin, or hæmagglutinin, produced in the serum of rabbits or fowls by inoculation of serum, or blood corpuscles, or their stroma from cases in a given group, gave a greater reaction with antigens (serum or r.b.c.) of that group than with those of another group. In respect of the two groups (1 and 4) dealt with, a large number of tests showed that there was *no group-specificity*. Fowls were injected intravenously and intraperitoneally, in the first case with repeated doses, in the latter with one large dose (20 c.cm.), only serum being injected. Rabbits were injected intravenously with repeated doses of all the antigens in question. An interesting point, meriting further investigation, emerged in the course of this experimental work; it was found that the anti-serum against stroma of red blood corpuscles produced, with the red blood corpuscles tested, agglutination much more frequently, or more strongly, than anti-serum obtained by injection of whole red blood corpuscles.

BRONCHOMONILIASIS.

BY TH. JOEKES, M.B. LEIDEN, M.R.C.S.,
LATE SENIOR DEMONSTRATOR OF PATHOLOGY,
ST. BARTHOLOMEW'S HOSPITAL;

AND

R. H. SIMPSON, M.D., M.R.C.P. LOND., D.P.H. OXF.,
ASSISTANT PHYSICIAN, EAST LONDON HOSPITAL; LATE
CHIEF ASSISTANT TO A MEDICAL UNIT,
ST. BARTHOLOMEW'S HOSPITAL.

ONLY within recent years has there been any general recognition of the frequency with which mycotic infections of the respiratory tract occur. In 1910 Castellani[1] drew attention to the part played by fungi of the genus Monilia, and published an account of 22 cases occurring in Ceylon. Since that time numerous other instances have been recorded, notably in Egypt,[2] Italy, and South America.[3] Cases have also been found in Siam,[4] China,[5] South Africa,[6] France, and elsewhere. In general it may be said that the maximum incidence occurs in climates which are both hot and moist. Fungi of the Monilia group are members of the family Oösporaceæ, to which class belong those of the closely allied genus Oidium. Outside the body they are widely distributed, and may be found more especially on fruit and on dead leaves and wood. In the sputum they appear as round or oval Gram-positive, yeast-like bodies, sometimes showing a double contour (Fig. 1). Fragments of mycelium may also be found, often in bacillary or coccoid forms. Not infrequently tiny white particles, representing masses of growth, may be visible to the naked eye.

Although cultures may be obtained on ordinary media, a more copious growth occurs in those which are slightly acid in reaction and contain a percentage of some sugar—e.g., glucose or maltose. Growth occurs readily at room temperature, but in some cases is more rapid at 37° C. On solid media (Fig. 3) the cultures are usually of a creamy-white colour; later, a brownish pigmentation often appears. They are composed of the yeast-like bodies only. In liquid media, bacillary and filamentous forms may be found (Fig. 2). Numerous species have now been isolated. For their identification, use has been made of their powers to ferment various "sugars" with the production of gas. Castellani has demonstrated that these powers are remarkably constant in freshly isolated strains, and on this basis has evolved a comprehensive classification.[7]

Infection in Man.

In man direct infection from case to case may possibly occur. More commonly, however, bronchomoniliasis results from the inhalation of contaminated particles. The relatively high incidence among tea-tasters in Ceylon confirms this view, and gives some indication of the importance of the occupational factor. The further possibility that pulmonary infection may occur by spread from a cutaneous source is suggested by the researches of Wade,[8] who succeeded in producing chronic lesions with cavitation in the lungs of a monkey after subcutaneous injection of a broth culture of *Blastomyces dermatitidis*. It is noteworthy that in cases of primary infection of the respiratory tract the mouth and pharynx usually escape. Secondary infection from this source may, however, occur in debilitated persons. Instances of mixed infection are not uncommon, notably with the tubercle bacillus or, in tropical countries, with *Spirochæta bronchialis* or *Paragonimus westermanni*.

however, Monilia was demonstrated in film and grown in pure culture. It would appear, therefore, that this procedure is of some diagnostic value.

(*b*) There is no record in published cases of resort to blood culture. In view of the possibility of generalisation of the infection, positive results might be expected in some instances. Cultures in sugar-broth media taken from Cases 2 and 3 of the above series proved sterile.

(*c*) Agglutination and complement-fixation tests are sometimes of value. No evidence of the presence of specific agglutination could be found in the sera of Cases 3 and 4, although after the administration of an autogenous vaccine agglutination occurred in Case 2 in serum dilutions from 1 in 5 to 1 in 50.

(*d*) In Cases 5 (*M. pinoyi*) and 4 (*M. guillermondi*) an attempt was made to establish the diagnosis by means of cutaneous inoculation of protein isolated from a culture of *Monilia pinoyi*. In neither instance did any reaction occur.

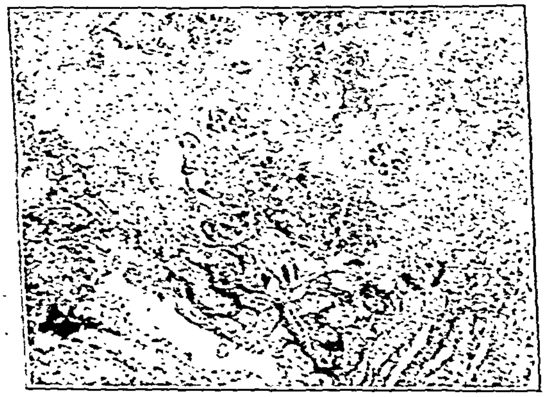
In those cases where the lesion is purely local those methods of investigation which aim at the detection of the organism in the circulation, or which depend on the recognition of specific general reactions, are hardly applicable. There is, however, evidence to suggest that dissemination does occur and that the use of these methods for diagnostic purposes is worthy of trial.

Treatment.

Authorities are unanimous in their opinion that the administration of iodine is beneficial. For oral administration potassium iodide in large doses is sometimes effective, although tinct. iodi. (French Codex) is perhaps a more active preparation. Castellani recommends saiodin (10–20 gr. t.d.s.) in cachet. For intramuscular injection lipiodol in doses of 1–2 c.cm. (0·54–1·08 g. iodine) daily is of use.

In the cases recorded above potassium iodide was administered in doses of from gr. xxx.–lx. per diem. The persistence of Monilia in the sputum after convalescence is due in part to the fact that the patients neglected treatment, and in part no doubt to the relative smallness of the doses ordered. Cases 2 and 4 were given autogenous vaccines in doses of from 10–2000 millions. No reaction of any kind was observed.

FIG. 4.



Miliary lesions resembling tubercles found in kidney of rabbit after intravenous injection of 5 c.cm. of a moderately turbid emulsion of *Monilia pinoyi* culture isolated from Case 2.

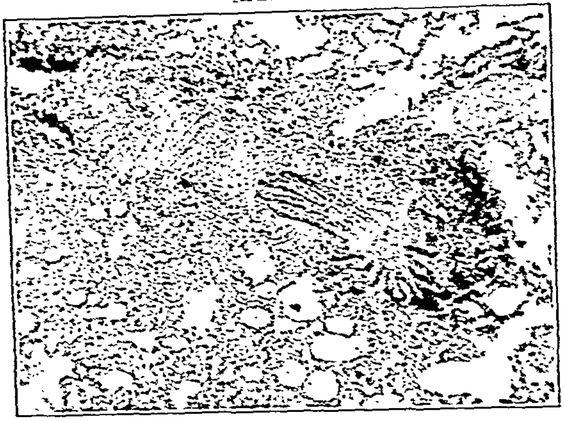
Prognosis.

Mild cases tend to recover spontaneously. There seems to be no doubt, however, that efficient treatment is capable of considerably modifying the course of both the mild and the more severe infections, and of producing a rapid improvement in many cases. To avoid, as far as possible, the danger of relapse, the patient should be kept under the influence of iodine for some time after convalescence is complete.

Conclusion.

In conclusion, it is suggested that bronchomoniliasis is of more frequent occurrence in this country than has hitherto been suspected, and that, as the clinical features are in no way distinctive, the investigation of sputa for the presence of fungi will well repay the trouble entailed.

FIG. 5.



Section of rabbit's lung showing marked peribronchial infiltration and small tubercles, composed chiefly of endothelial and plasma cells and having hyaline non-caseating centres.

We wish to thank Dr. H. H. Tooth and Sir Thomas Horder for permission to investigate and to publish these cases and, more especially, for the kindly interest which they have taken in our work.

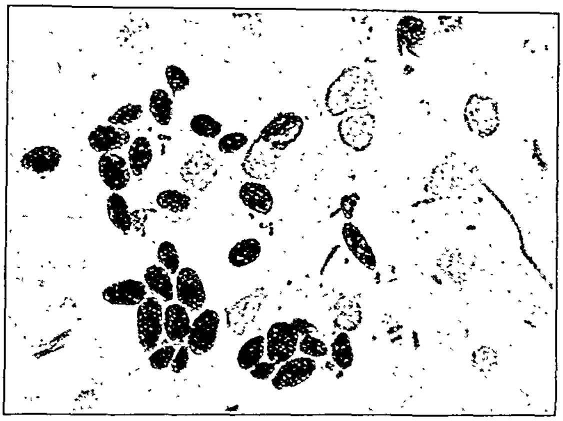
exudation occurring in the fifth week. The sputum was copious and frothy at first; later it became more scanty and tenacious. In films were numerous *Gram-positive* diplococci and filaments. Culture yielded a growth of pneumococci (type 2) and of *Monilia pinoyi.*

The patient was last seen ten weeks after the onset of her illness. She was in good health, the amount of sputum was very small, but still contained Monilia.

CASE 4.—A woman of 47, a needleworker, was admitted to hospital under the care of Dr. Tooth in April, 1921, complaining of malaise and obscure pain in the right side of the chest. An area of consolidation was present at the base of the right lung, over which coarse pleural friction was audible. A few days later a further area of consolidation appeared at the base of the left lung. Recovery was gradual and uninterrupted. The temperature remained raised for 14 days, and fell to normal by lysis. The signs of consolidation, however, did not wholly disappear for some weeks.

FIG. 1.

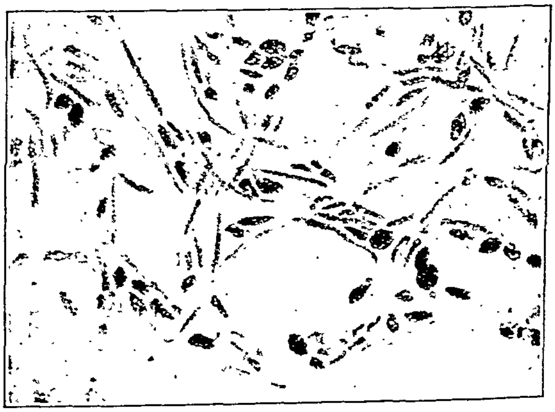


Fungi of Monilia group in sputum, appearing as round or oval yeast-like bodies.

The sputum in this case was never copious. Repeated cultures on Sabouraud's medium yielded a plentiful growth of *Monilia guillermondi.*

CASE 5.—A girl of 15, a blouse machinist, was admitted to hospital in May, 1921, under the care of Dr. Tooth, suffering from cardiac failure, following a recent attack of rheumatic fever. She was febrile, and coughed up a moderately large amount of muco-purulent sputum, from which a profuse growth of *Monilia pinoyi* was obtained on several occasions. Signs of consolidation were present at the base of the left lung. After a few days generalised râles and friction at the base of the right lung appeared. Later 28 c.cm. of clear, sterile, straw-coloured fluid were removed by aspiration from the left pleural cavity. The patient's cardiac condition failed to improve. She died two months after admission. Autopsy revealed the presence of severe lesions in the heart. There was a small amount of fluid in both pleural cavities. The lungs were very œdematous but otherwise normal.

FIG. 2.



Bacillary and filamentous forms found in liquid media.

Unfortunately, no detailed examination was made for evidence of Monilia infection.

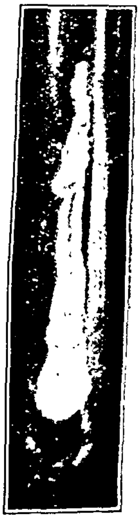
The following case is an instance of mixed infection with Monilia and the tubercle bacillus, and is of interest because, as the diagnosis of phthisis appeared clear, the sputum was included in the number of that examined as controls.

CASE 6.—A housewife, aged 24, was admitted in December, 1921, under the care of Sir Thomas Horder. She had been in poor health for four months, during the last of which she had been confined to bed, and had lost weight rapidly. Cough was troublesome, with expectoration of much muco-purulent material. On several occasions examination showed the presence of large numbers of tubercle bacilli, of pneumococci, and also of *Monilia pinoyi*, both in yeast-like and filamentous forms. The patient remained under observation for two months, during which time her condition steadily deteriorated.

Although it would appear that the various species of Monilia are widely distributed, records of published cases give some indication of the local predominance of certain of them—e.g. *M. pinoyi* in Egypt and *M. tropicalis* in Ceylon. It is interesting, therefore, to note that from four out of five of the cases above recorded *M. pinoyi* was isolated. In only two of the cases (2 and 3) does the influence of a dusty occupation as to cause of infection seem to be at all possible. In Case 2 the history of the occurrence of pustules on the arms and faces of workers seems suggestive. Attempts to isolate Monilia from a sample of the suspected straw (Case 2) and from the dust of various brands of cigarettes (Case 3) failed.

The clinical picture in no way presents any distinctive feature. The long duration of the signs of pulmonary consolidation is notable, as is the persistence of the fungus in the sputum after the completion of convalescence—a feature indicative of the chronicity of the infection, and perhaps of the possibility of relapse. In the two cases which presented an acute tonsillitis cultures made from the exudate yielded a plentiful growth of *Monilia pinoyi.* It is difficult, however, to exclude the possibility of contamination from the sputum.

FIG. 3.



Creamy-white culture on solid media in test-tube.

Diagnosis.

The diagnosis of bronchomoniliasis is by no means free from difficulty. It depends primarily on the repeated demonstration of the fungus in the sputum. It is essential that specimens should be collected into sterile vessels and washed repeatedly before cultivation. The patient should gargle with sterile saline or with a dilute solution of potassium permanganate before expectorating. In cases of true infection a profuse growth occurs from cultures on Sabouraud's medium. In other cases experience has shown that, even when the preliminary washing of the patient's mouth is neglected, it is exceptional to obtain more than a very scanty growth, and that commonly none at all appears. This fact has been established by the examination and cultivation of a large number of sputa selected at random without reference to the clinical diagnosis. Confirmatory evidence may be sought in other directions.

(*a*) Fixation abscess: *In Case* 2 the hypodermic administration of digitalin resulted on three *occasions in* the production of small abscesses containing *Monilia pinoyi* in pure culture. This *fact* was interpreted as an indication that a true and generalised infection existed. As a further step, small fixation abscesses were produced in Cases 3, 4, and 6 by means of the hypodermic injection of a few minims of oil of turpentine. In Cases 3 and 6 the pus was sterile. *In Case* 4.

however, Monilia was demonstrated in film and grown in pure culture. It would appear, therefore, that this procedure is of some diagnostic value.

(b) There is no record in published cases of resort to blood culture. In view of the possibility of generalisation of the infection, positive results might be expected in some instances. Cultures in sugar-broth media taken from Cases 2 and 3 of the above series proved sterile.

(c) Agglutination and complement-fixation tests are sometimes of value. No evidence of the presence of specific agglutination could be found in the sera of Cases 3 and 4, although after the administration of an autogenous vaccine agglutination occurred in Case 2 in serum dilutions from 1 in 5 to 1 in 50.

(d) In Cases 5 (*M. pinoyi*) and 4 (*M. guillermondi*) an attempt was made to establish the diagnosis by means of cutaneous inoculation of protein isolated from a culture of *Monilia pinoyi*. In neither instance did any reaction occur.

In those cases where the lesion is purely local those methods of investigation which aim at the detection of the organism in the circulation, or which depend on the recognition of specific general reactions, are hardly applicable. There is, however, evidence to suggest that dissemination does occur and that the use of these methods for diagnostic purposes is worthy of trial.

Treatment.

Authorities are unanimous in their opinion that the administration of iodine is beneficial. For oral administration potassium iodide in large doses is sometimes effective, although tinct. iodi. (French Codex) is perhaps a more active preparation. Castellani recommends saiodin (10–20 gr. t.d.s.) in cachet. For intramuscular injection lipiodol in doses of 1–2 c.cm. (0·54–1·08 g. iodine) daily is of use.

In the cases recorded above potassium iodide was administered in doses of from gr. xxx.–lx. per diem. The persistence of Monilia in the sputum after convalescence is due in part to the fact that the patients neglected treatment, and in part no doubt to the relative smallness of the doses ordered. Cases 2 and 4 were given autogenous vaccines in doses of from 10–2000 millions. No reaction of any kind was observed.

FIG. 4.

MENTAL TESTS FOR DELINQUENTS,

AND MENTAL CONFLICT AS A CAUSE OF DELINQUENCY.

By M. HAMBLIN SMITH, M.D. Durh.,
MEDICAL OFFICER, H.M. PRISON, BIRMINGHAM;
AND
G. W. PAILTHORPE, M.B., B.S. Durh.

The first part of this paper deals with the results obtained with the Hamblin Smith scheme of tests[1] on prisoners in Birmingham Prison. Of 750 cases tested during a period of three years, only those have been considered for the purposes of this paper in which a complete examination with these tests was given. This condition has excluded, amongst others, a considerable number of imbeciles. Of these completely examined cases there were 217 men and 108 women. It must be taken into consideration that there were a number of cases remitted for special investigation under the Birmingham scheme,[2] and many of these were prima facie abnormal. No conclusions, therefore, must be drawn from our figures as to the percentage of mental defectives and subnormals amongst our criminals.

Examination of 325 Cases.

The results arrived at after the examination of these 325 persons suggest conclusions which further investigation on a more extensive scale is needed to corroborate. We are, therefore, presenting suggestions and indications rather than statistics. The cases have been grouped under the headings of normal (N), subnormal (S), and mental defective (M.D.). (Table I.)

TABLE I.

	N.	S.	M.D.
Males	106	46	65
Females	45	22	41

Note.—This table must be kept in view throughout. All percentages throughout the paper are calculated on the basis of the figures here given.

The *normal* group needs no special description. The *subnormal* group consists of: (1) Persons considered to be defective in intelligence, in whom the defect is not great enough to warrant placing them in the mentally defective class, or where there was difficulty in establishing the existence of the defect from an early age. (2) Persons in whom the defect in intelligence is complicated by and in some cases brought about by mental conflict. The *mental defective* group are those who are certifiable under the 1913 Mental Deficiency Act—i.e., they present all the criteria of permanent mental defect from an early age, with need for care, supervision, and control for their own protection or the protection of others. Of the total 325 cases all except 28 were under the age of 30 years. The remainder were either subnormal or mentally defective. We have found that mentally normal persons over the age of 30 do not respond well, as a rule, to formal testing. The remaining 297 cases were quite unselected.

The total 325 cases have been classified as under:—

1. Under the headings normal, subnormal, and mental defective: (*a*) Results obtained in each of ten tests, summarised in Table II., are briefly explained and discussed. (*b*) The character of offences committed.

2. The normal and subnormal cases in connexion with mental conflict have been dealt with.

3. A general summing up of the results obtained is given.

Details of Tests.

Test 1. *Money Change.*—In this test the subject is asked simple questions such as: If your fare on a tram were 2½*d.* and you gave the conductor a 2*s.* piece, what change should you get? If you buy 1 lb. of bacon at 1*s.* 5*d.* the pound, what change should you have out of half-a-crown? "A kind of problem that must be solved if a subject is to live at all in the ordinary world." The gradation is definitely downwards; but it is to be noted that rather more than half the mentally defective are able to pass this test. The normal female shows a slightly better result than the normal male. This is probably due to the fact that women do the marketing and are, therefore, more constantly having to use this form of mental activity than the male.

Test 2. *First Form Board* (*Healy*).—The board is a rectangular frame into which exactly fit five blocks. It is a test of attention, perseverance, perception of form relationship and the ability to plan a simple piece of work. Again, the gradation is downwards. The males show a better result than the females. Since men are frequently engaged in work such as carpentry, brick-laying, plumbing, van-loading, road-making, &c., all of which require some skill in planning and fitting, it may be concluded that the difference is again, probably, due to occupation. The same variation is evident also in the second form board and in both boards taken together.

Test 3. *Second Form Board* (*Hamblin Smith*).—This is similar to the first form board test but more difficult, requiring a higher degree of intelligence to accomplish it. As we should expect, the gradation is very much more marked. Where 56·9 per cent. of mental defectives among the males were able to do the first form board, only 38·4 per cent. were able to do the second form board. Among the females the percentage for the first form board is 43·9 as against 21·9 for the second. Taking Tests 2 and 3 together we see that the percentage in the mental defective group is very much lower. The two tests, especially when taken together, form decidedly good discriminating tests for mental defect.

Test 4. *Aussage.*—A test of attention, observation, memory, and suggestibility. The subject is given a brightly coloured picture, being told to observe carefully all that he sees therein. After 20 seconds the picture is taken away, and he is told to give a full description of everything that he has noticed. After having exhausted these memories the examiner suggests certain objects as having been in the picture, and notice is taken as to whether the subject accepts these suggestions or not. The table shows the percentages of those found to be suggestible. *It will be noted that suggestibility rises with the decline of intelligence*, also that the males show a slightly greater degree of suggestibility than do the females.

Test 5. *Interpretation of Pictures* (*Terman*).—This is a test of apperception, recognition of a situation presented visually, and imagination. Two pictures are given in turn to the subject, and he is asked to give an interpretation of their meaning. The descent is very marked, and the test is correspondingly valuable. The females make a slightly better show than the males, perhaps indicating a slightly greater power of imagination.

Test 6. *Comparison of Lines* (*Binet*).—*A test of suggestibility.* Three pairs of unequal lines, the longer being, in each case, on the right-hand side, followed by three pairs of equal lines, are presented to the subject in succession. The suggestible subject is liable, because of the repetition in the first three pairs of the longer line being on the right-hand side, to see a longer line on the right-hand side in the case of the equal pairs also. There is a marked increase of suggestibility in the mentally defective class. *As in Test 4*, the males show a greater degree of suggestibility than the females. This difference may be due to the more secluded life of the female of the type with whom we are dealing and to her more guarded contact with the outer world; the male, who is more accustomed to meet other people, is less suspicious.

---

[1] The Psychology of the Criminal, Hamblin Smith, Chapter 2.

[2] The Medical Examination of Delinquents, Journal of Mental Science, July, 1922.

TEST 7. *Cricket Ball* (*Terman*).—A circle of about 3 inches in diameter, with a gap to represent a gate, is presented to the subject. He is asked to suppose he has lost a ball or a purse in this field, and to draw a line from the gate indicating the path he would take in order to find the lost object. The test is one of ability to grasp essentials, to comprehend simple directions, and to make a plan. The result may be a superior plan, an inferior plan, or no plan at all. Table II. shows the percentage able to produce a superior plan. The descent is very marked and the test very valuable. Males are better than females, probably for the same reasons as in Tests 1 and 2.

TEST 8. *Apperception Test* (*Heilbronner*).—This consists of eight sets of cards, each successive card in the set showing rather more detail in the representation of some common object (lamp, bicycle, &c.), until the complete object is shown in the final card. The cards in each set are presented in their order, and a note is made of the point at which the subject names correctly the object shown. A success is scored when the subject recognises the object in at least five of the eight sets before more than half the cards in each set have been shown. Apperception is naturally less strong in the subnormals and the mentally defective. The difference between the sexes is not appreciable.

TEST 9. *Pictorial Completion Test* (*Healy*).—A test demanding mental control, association, imagination, and apperception. It consists of a brightly coloured picture, mounted on wood, and in which 10 1-inch squares have been cut out. The subject is given the picture and 45 blocks, each 1 inch square, of which 40 bear a representation of some object, while the other five are blanks. He is required to fill in the picture with the blocks which, in his opinion, make the best sense. Care is taken to see that he thoroughly understands what he has to do by means of the demonstration of the correct filling of one space by the examiner. The subject is then left to complete the picture by himself. A note is made of final errors, logical and illogical, the latter being errors for which the subject can give no reasonable explanation. The gradation is very marked, and this pictorial completion forms a most excellent discriminating test. The opinion expressed in "Psychology of the Criminal," p. 42, that an absolutely complete success in this test excludes mental defect, still holds good. In our present figures, however, we have scored more leniently, allowing a wrong window, a wrong bird, and a pumpkin instead of a ball to count as logical and a pass.

TEST 10. *Information*.—A test of general current knowledge, involving simple questions such as the name of the King and the Prince of Wales, the names of four or five large cities in England, the cause of the Great War and the date of its commencement, the names of our allies and those of Germany, and so on. This table includes cases whose information was scored as "very good, "good," or "fair." The results are as expected. There is a great falling off in the mentally defective class. Here, again, the males are better than the females, a result we should expect, since men, by reason of their manifold occupations, are brought in contact with the outer world, whereas the women of the class from which we draw our offenders are often occupied at home.

Summing up the results obtained on the ten tests. Table III. shows the averages of failures in each case. These averages rise rapidly in the subnormal and mentally defective groups.

TABLE III.—*Showing Averages of Failures in each of the Tests.*

—		N.	S.	M.D.
Males ..	No. of cases..	106	46	65
	No. of failures	198	197	552
	Average per person ..	1·88	4·37	8·76
Females	No. of cases..	45	22	41
	No. of failures	101	121	333
	Average per person ..	2·24	5·5	8·1

Table III. also shows the averages in the normal and the subnormal classes on the male side to be better than on the female side. This is what we should expect, since Tests 2, 3, 6, 7, 8, and 9 give in each case a better result for the male, an explanation of which has been suggested on occupational grounds. In Tests 1 and 5 the female is better than the male, probably from the same cause. In Tests 4 and 6 it should be noted that the males are more suggestible than the females.

We venture to think that, for reasons set out in detail in the "Psychology of the Criminal," pp. 46-8, this scheme of tests possesses certain advantages over the well-known Terman scheme, as well as avoiding certain possible fallacies, especially for use with subjects between the ages of 16 and 30 years. The tests require little facility in the use of language, and are, therefore, very useful when we deal with the subnormal or defective "verbalist" type.[3]

Classification of Offences.

Classifying the cases under offences, we have divided them into four groups:—

(*a*) *Larceny.*—Offences of dishonesty of every kind, from trivial stealing to obtaining money on false pretences.

(*b*) *Sex.*—The character of offences in this class on the part of the males is largely that of indecent exposure and indecent assault, whereas in the female the offence in most cases is that of solicitation. That is to say, that while in the male the offence is purely sexual in character, in the female the offence is activated largely, and in some cases solely, by economic reasons.

(*c*) *Vagrancy.*—This includes all such offences as begging and wandering without visible means of support.

(*d*) *Miscellaneous.*—A comparatively small group, including drunkenness, violence, attempted suicide, &c.

Table IV. shows the percentages of cases arranged under each group.

TABLE IV.—*Showing the Percentage of Cases arranged under each Group.*

—		N.	S.	M.D.
Males ..	Larceny	68·9	50·0	41·5
	Sex	20·8	21·7	26·2
	Vagrancy	7·2	13·0	21·5
	Other offences	3·1	15·3	10·8
Females	Larceny	52·2	38·1	25·0
	Sex	13·5	28·8	25·0
	Vagrancy	10·5	4·1	27·5
	Other offences	23·8	28·0	22·5

The great preponderance of larceny and sex offences over all others is clearly seen. These two offences will always provide the vast majority of the cases to be investigated.

The Factor of Mental Conflict.

We now take the normal and subnormal groups, and give below in Table V. the percentage of cases in which the offence committed was due to mental conflict. No conclusions, however, as to the incidence of mental conflict as a cause of delinquency must be drawn from these figures, since many of these cases were sent for special observation. Further, some of the cases were not examined sufficiently deeply to ascertain whether mental conflict were present or not. The short period of detention of many of the subjects, as well as on our part the lack of the necessary time, have been obstacles to deeper and more extensive investigation. But we have often gone far enough to see that a mental conflict, deserving fuller investigation, is a prominent factor in many cases. And we feel that mental conflict is the most important single cause of delinquency amongst the normal and subnormal offenders.

TABLE V.—*Mental Conflict Cases.*

	N.		S.
Males	32·0	....	41·3
Females	33·3	....	13·6

The figures in Table V. represent altogether 70 mental conflict cases; and these, under the head of offences, are divided up as below: larceny, 50 per cent.; sex, 28·3 per cent.; other offences, 21·7 per cent. In dealing with these cases we have found without exception that the conflict has been of a sex nature, although the offence committed may be of an entirely different character—e.g., stealing, violence, drunkenness, &c. As an example, a woman was brought up

MENTAL TESTS FOR DELINQUENTS,

AND MENTAL CONFLICT AS A CAUSE OF DELINQUENCY.

BY M. HAMBLIN SMITH, M.D. DURH.,
MEDICAL OFFICER, H.M. PRISON, BIRMINGHAM;
AND
G. W. PAILTHORPE, M.B., B.S. DURH.

THE first part of this paper deals with the results obtained with the Hamblin Smith scheme of tests[1] on prisoners in Birmingham Prison. Of 750 cases tested during a period of three years, only those have been considered for the purposes of this paper in which a complete examination with these tests was given. This condition has excluded, amongst others, a considerable number of imbeciles. Of these completely examined cases there were 217 men and 108 women. It must be taken into consideration that there were a number of cases remitted for special investigation under the Birmingham scheme,[2] and many of these were prima facie abnormal. No conclusions, therefore, must be drawn from our figures as to the percentage of mental defectives and subnormals amongst our criminals.

Examination of 325 Cases.

The results arrived at after the examination of these 325 persons suggest conclusions which further investigation on a more extensive scale is needed to corroborate. We are, therefore, presenting suggestions and indications rather than statistics. The cases have been grouped under the headings of normal (N), subnormal (S), and mental defective (M.D.). (Table I.)

TABLE I.

	N.	S.	M.D.
Males	106	46	65
Females	45	22	41

Note.—This table must be kept in view throughout. All percentages throughout the paper are calculated on the basis of the figures here given.

The *normal* group needs no special description. The *subnormal* group consists of: (1) Persons considered to be defective in intelligence, in whom the defect is not great enough to warrant placing them in the mentally defective class, or where there was difficulty in establishing the existence of the defect from an early age. (2) Persons in whom the defect in intelligence is complicated by and in some cases brought about by mental conflict. The *mental defective* group are those who are certifiable under the 1913 Mental Deficiency Act—i.e., they present all the criteria of permanent mental defect from an early age, with need for care, supervision, and control for their own protection or the protection of others. Of the total 325 cases all except 28 were under the age of 30 years. The remainder were either subnormal or mentally defective. We have found that mentally normal persons over the age of 30 do not respond well, as a rule, to formal testing. The remaining 297 cases were quite unselected.

The total 325 cases have been classified as under:—

1. Under the headings normal, subnormal, and mental defective: (*a*) Results obtained in each of ten tests, summarised in Table II., are briefly explained and discussed. (*b*) The character of offences committed.

2. The normal and subnormal cases in connexion with mental conflict have been dealt with.

3. A general summing up of the results obtained is given.

Details of Tests.

TEST 1. *Money Change.*—In this test the subject is asked simple questions such as: If your fare on a tram were 2½*d.* and you gave the conductor a 2*s.* piece, what change should you get? If you buy 1 lb. of bacon at 1*s.* 5*d.* the pound, what change should you have out of half-a-crown? "A kind of problem that must be solved if a subject is to live at all in the ordinary world." The gradation is definitely downwards; but it is to be noted that rather more than half the mentally defective are able to pass this test. The normal female shows a slightly better result than the normal male. This is probably due to the fact that women do the marketing and are, therefore, more constantly having to use this form of mental activity than the male.

TABLE II.—*Summary of Results Obtained in Ten Tests.*

—		Sex.	N.	S.	M.D.
Test 1.	Percentage of success ..	M.	97·8	83·7	54·9

,, 7.	Percentage of superior plan	M.	68·0	39·1	17·5
		F.	53·4	30·0	5·4
,, 8.	Percentage of success ..	M.	86·6	64·9	61·2
		F.	89·2	62·1	48·5
,, 9.		M.	71·7	30·2	15·6
		F.	51·1	19·0	5·4
,, 10.	Percentage of very good, good, or fair	M.	93·0	81·4	20·9
		F.	81·2	66·6	31·0

TEST 2. *First Form Board* (*Healy*).—The board is a rectangular frame into which exactly fit five blocks. It is a test of attention, perseverance, perception of form relationship and the ability to plan a simple piece of work. Again, the gradation is downwards. The males show a better result than the females. Since men are frequently engaged in work such as carpentry, brick-laying, plumbing, van-loading, road-making, &c., all of which require some skill in planning and fitting, it may be concluded that the difference is again, probably, due to occupation. The same variation is evident also in the second form board and in both boards taken together.

TEST 3. *Second Form Board* (*Hamblin Smith*).—This is similar to the first form board test but more difficult, requiring a higher degree of intelligence to accomplish it. As we should expect, the gradation is very much more marked. Where 56·9 per cent. of mental defectives among the males were able to do the first form board, only 38·4 per cent. were able to do the second form board. Among the females the percentage for the first form board is 43·9 as against 21·9 for the second. Taking Tests 2 and 3 together we see that the percentage in the mental defective group is very much lower. The two tests, especially when taken together, form decidedly good discriminating tests for mental defect.

TEST 4. *Aussage.*—A test of attention, observation, memory, and suggestibility. The subject is given a brightly coloured picture, being told to observe carefully all that he sees therein. After 20 seconds the picture is taken away, and he is told to give a full description of everything that he has noticed. After having exhausted these memories the examiner suggests certain objects as having been in the picture, and notice is taken as to whether the subject accepts these suggestions or not. The table shows the percentages of those found to be suggestible. It will be noted that suggestibility rises with the decline of intelligence, also that the males show a slightly greater degree of suggestibility than do the females.

TEST 5. *Interpretation of Pictures* (*Terman*).—This is a test of apperception, recognition of a situation presented visually, and imagination. Two pictures are given in turn to the subject, and he is asked to give an interpretation of their meaning. The descent is very marked, and the test is correspondingly valuable. The females make a slightly better show than the males, perhaps indicating a slightly greater power of imagination.

TEST 6. *Comparison of Lines* (*Binet*).—A test of suggestibility. Three pairs of unequal lines, the longer being, in each case, on the right-hand side, followed by three pairs of equal lines, are presented to the subject in succession. The suggestible subject is liable, because of the repetition in the first three pairs of the longer line being on the right-hand side, to see a longer line on the right-hand side in the case of the equal pairs also. There is a marked increase of suggestibility in the mentally defective class. As in Test 4, the males show a greater degree of suggestibility than the females. This difference may be due to the more secluded life of the female of the type with whom we are dealing and to her more guarded contact with the outer world; the male, who is more accustomed to meet other people, is less suspicious.

---

[1] The Psychology of the Criminal, Hamblin Smith, Chapter 2.

[2] The Medical Examination of Delinquents, Journal of Mental Science, July, 1922.

TEST 7. *Cricket Ball* (*Terman*).—A circle of about 3 inches in diameter, with a gap to represent a gate, is presented to the subject. He is asked to suppose he has lost a ball or a purse in this field, and to draw a line from the gate indicating the path he would take in order to find the lost object. The test is one of ability to grasp essentials, to comprehend simple directions, and to make a plan. The result may be a superior plan, an inferior plan, or no plan at all. Table II. shows the percentage able to produce a superior plan. The descent is very marked and the test very valuable. Males are better than females; probably for the same reasons as in Tests 1 and 2.

TEST 8. *Apperception Test* (*Heilbronner*).—This consists of eight sets of cards, each successive card in the set showing rather more detail in the representation of some common object (lamp, bicycle, &c.), until the complete object is shown in the final card. The cards in each set are presented in their order, and a note is made of the point at which the subject names correctly the object shown. A success is scored when the subject recognises the object in at least five of the eight sets before more than half the cards in each set have been shown. Apperception is naturally less strong in the subnormals and the mentally defective. The difference between the sexes is not appreciable.

TEST 9. *Pictorial Completion Test* (*Healy*).—A test demanding mental control, association, imagination, and apperception. It consists of a brightly coloured picture, mounted on wood, and in which 10 1-inch squares have been cut out. The subject is given the picture and 45 blocks, each 1 inch square, of which 40 bear a representation of some object, while the other five are blanks. He is required to fill in the picture with the blocks which, in his opinion, make the best sense. Care is taken to see that he thoroughly understands what he has to do by means of the demonstration of the correct filling of one space by the examiner. The subject is then left to complete the picture by himself. A note is made of final errors, logical and illogical, the latter being errors for which the subject can give no reasonable explanation. The gradation is very marked, and this pictorial completion forms a most excellent discriminating test. The opinion expressed in "Psychology of the Criminal," p. 42, that an absolutely complete success in this test excludes mental defect, still holds good. In our present figures, however, we have scored more leniently, allowing a wrong window, a wrong bird, and a pumpkin instead of a ball to count as logical and a pass.

TEST 10. *Information*.—A test of general current knowledge, involving simple questions such as the name of the King and the Prince of Wales, the names of four or five large cities in England, the cause of the Great War and the date of its commencement, the names of our allies and those of Germany, and so on. This table includes cases whose information was scored as "very good, "good," or "fair." The results are as expected. There is a great falling off in the mentally defective class. Here, again, the males are better than the females, a result we should expect, since men, by reason of their manifold occupations, are brought in contact with the outer world, whereas the women of the class from which we draw our offenders are often occupied at home.

Summing up the results obtained on the ten tests, Table III. shows the averages of failures in each case. These averages rise rapidly in the subnormal and mentally defective groups.

TABLE III.—*Showing Averages of Failures in each of the Tests.*

—		N.	S.	M.D.
Males ..	No. of cases..	106	46	65
	No. of failures	198	197	552
	Average per person ..	1·88	4·37	8·76
Females	No. of cases..	45	22	41
	No. of failures	101	121	333
	Average per person ..	2·24	5·5	8·1

Table III. also shows the averages in the normal and the subnormal classes on the male side to be better than on the female side. This is what we should expect, since Tests 2, 3, 6, 7, 8, and 9 give in each case a better result for the male, an explanation of which has been suggested on occupational grounds. In Tests 1 and 5 the female is better than the male, probably from the same cause. In Tests 4 and 6 it should be noted that the males are more suggestible than the females.

We venture to think that, for reasons set out in detail in the "Psychology of the Criminal," pp. 46-8, this scheme of tests possesses certain advantages over the well-known Terman scheme, as well as avoiding certain possible fallacies, especially for use with subjects between the ages of 16 and 30 years. The tests require little facility in the use of language, and are, therefore, very useful when we deal with the subnormal or defective "verbalist" type.[3]

Classification of Offences.

Classifying the cases under offences, we have divided them into four groups:—

(*a*) *Larceny.*—Offences of dishonesty of every kind, from trivial stealing to obtaining money on false pretences.

(*b*) *Sex.*—The character of offences in this class on the part of the males is largely that of indecent exposure and indecent assault, whereas in the female the offence in most cases is that of solicitation. That is to say, that while in the male the offence is purely sexual in character, in the female the offence is activated largely, and in some cases solely, by economic reasons.

(*c*) *Vagrancy.*—This includes all such offences as begging and wandering without visible means of support.

(*d*) *Miscellaneous.*—A comparatively small group, including drunkenness, violence, attempted suicide, &c.

Table IV. shows the percentages of cases arranged under each group.

TABLE IV.—*Showing the Percentage of Cases arranged under each Group.*

—		N.	S.	M.D.
Males ..	Larceny	68·9	50·0	41·5
	Sex	20·8	21·7	26·2
	Vagrancy	7·2	13·0	21·5
	Other offences	3·1	15·3	10·8
Females	Larceny	52·2	38·1	25·0
	Sex	13·5	28·8	25·0
	Vagrancy	10·5	4·1	27·5
	Other offences	23·8	28·0	22·5

The great preponderance of larceny and sex offences over all others is clearly seen. These two offences will always provide the vast majority of the cases to be investigated.

The Factor of Mental Conflict.

We now take the normal and subnormal groups, and give below in Table V. the percentage of cases in which the offence committed was due to mental conflict. No conclusions, however, as to the incidence of mental conflict as a cause of delinquency must be drawn from these figures, since many of these cases were sent for special observation. Further, some of the cases were not examined sufficiently deeply to ascertain whether mental conflict were present or not. The short period of detention of many of the subjects, as well as on our part the lack of the necessary time, have been obstacles to deeper and more extensive investigation. But we have often gone far enough to see that a mental conflict, deserving fuller investigation, is a prominent factor in many cases. And we feel that mental conflict is the most important single cause of delinquency amongst the normal and subnormal offenders.

TABLE V.—*Mental Conflict Cases.*

	N.	S.
Males	32·0	41·3
Females	33·3	13·6

The figures in Table V. represent altogether 70 mental conflict cases; and these, under the head of offences, are divided up as below: larceny, 50 per cent.; sex, 28·3 per cent.; other offences, 21·7 per cent. In dealing with these cases we have found without exception that the conflict has been of a sex nature, although the offence committed may be of an entirely different character—e.g., stealing, violence, drunkenness, &c. As an example, a woman was brought up before the courts on the charge of wilful destruction of public property; analysis proved the meaning of the act to be an attempt at expression on the part of a repressed complex which had originated in a sex experience many years before. The act was, in fact, an attempt on the part of the patient at protection against her unconscious. It is, moreover, to be noticed that sexual offences in the male, such as indecent behaviour, are, in the female, where repression of sex impulses has been more generally practised, often substituted by other offences, such as violence, attempted suicide, drunkenness, &c.

---

[3] Healy: "The Individual Delinquent," pp. 501, ff.

In summing up, therefore, we venture to think that our findings indicate at least one thing—that is, the enormous importance of conflict as a cause of delinquency. We are well aware that there is much that is highly controversial in this subject, and that very diverse views are held as to the precise mechanism and character of conflict and repression, and the manner of its operation. Into this controversy it is not our intention to enter. Nor does it greatly matter, from a practical point of view, which particular theory is adopted. It is the effect of repression and conflict which concerns us. And upon this there is more unanimity of opinion. To take an example from a somewhat cognate subject. There are great divergences of view as to the mechanism of production of dementia præcox; but there is no difficulty in the recognition of well-marked cases of that condition. Nor is there divergence of opinion as to the way in which these cases are to be dealt with. So with repression and conflict. Until such time as the present controversies have composed themselves, it is open to us to adopt any of the varying views. But there can be no doubt as to the importance of the condition. Nor can there be uncertainty as to the desirability of proper psychological investigation and treatment of this condition, nor the failure of our present methods in this respect. And the recognition of the importance of this condition as a cause of delinquency in no way implies that the subjects thereof are to be simply allowed to do whatever they please. The welfare of society is of supreme importance. Our point is that these cases require treatment, in the interests of society as well as in their own, and that this treatment must be on special lines.

What is wanted is: (*a*) Recognition of these conflict cases by means of full investigation before trial; (*b*) appreciation by the courts of the value and the necessity of the treatment of these cases of conflict; (*c*) provision of means of treating these cases by (1) proper institutions, (2) perhaps some form of indeterminate sentence.

The willingness of the patient is essential for the treatment, for which reason we think that the probation system might well be combined, in certain of these cases, with remedial measures. The submission to such measures could be made a condition of probation. But this involves institutions at which, and practitioners by whom, this treatment can be carried out.

The publication of this paper, as expressing our personal views, is approved by the Prison Commissioners.

RENDLESHAM HALL, SUFFOLK.—The new sanatorium for the residential treatment of alcoholism and drug addiction, which was described in THE LANCET of May 5th last, is now in full working order, and a descriptive booklet has been issued which gives full particulars of the conditions under which the treatment, founded on voluntary lines with an eye to the physical comfort and general well-being of the patient, is carried out. How exactly suitable these conditions are is shown by the illustrations of sumptuous interiors and the charming prospects of beautiful old trees, delightful walks, and well-kept gardens. There is also every facility for indoor recreations. Rendlesham Hall stands in 270 acres of its own grounds and in the centre of some 5000 acres of preserved land, full of game, and is an ideal place for the purpose for which it is intended, having all the charm of a large country mansion with effective medical treatment on the spot. The London offices are at 20, Ridge road, Stroud Green, London, N.8, from where the pamphlet can be obtained from the Secretary of Norwood Sanatorium, Limited.

THE INTER-RELATIONSHIP OF BLOOD-FAT AND BLOOD-SUGAR.

BY T. H. OLIVER, M.D. MANCH., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, MANCHESTER;
AND
A. HAWORTH, M.SC., M.B., CH.B. MANCH.,
ASSISTANT LECTURER IN CHEMICAL PATHOLOGY,
VICTORIA UNIVERSITY, MANCHESTER.

THE presence of lipæmia and acetonuria in nearly all conditions in which there is a disturbance of carbohydrate metabolism has suggested to many observers the intimate relationship of the fat and sugar in the body. Whether ketosis can be explained entirely by a deficiency of oxidising carbohydrate, or whether it is due also to a disturbance of a physical or chemical combination of the two substances, is a problem which has yet to be solved. Some years ago Newburgh and Marsh[1] demonstrated the ease with which ketosis may clear up in certain cases of diabetes, in spite of a high fat dietary, and we have observed in several cases of severe diabetes an almost complete disappearance of acetonuria where the sole dietary has consisted of 3 oz. of cod-liver oil daily. In one instance the daily acetone excretion fell from 3 to 0·2 g. within six days and was accompanied by a rise in the alveolar CO_2 and a general amelioration of the patient's condition. These phenomena are difficult of explanation if carbohydrate be looked upon as a necessary fuel for the combustion of fat. *On the other hand, excess of fat in the diabetic dietary is a frequent source of glycosuria, as has been pointed out by Allen, and it was noticeable in our own cases, above mentioned, that the glycosuria took much longer to clear up than with starvation alone, in spite of the rapid fall of acetone excretion.*

There is some experimental evidence of an inter-relationship between the two substances. Biedl many years ago produced glycosuria by ligature of the thoracic duct, and though the experiment has been confirmed by others the result has been variously attributed to nervous irritation, an interference with a pancreatic secretion travelling via the duct, or to a disturbance of fat metabolism. The occasional coincidence of chyluria and glycosuria in man suggests, however, that the last explanation is the more probable. In one such case under the care of Dr. G. R. Murray, which we had the opportunity of observing, these symptoms appeared to be associated with a disturbance of liver function, as they were accompanied by temporary enlargement of that organ and by jaundice. Again, in phosphorus poisoning, where there is much disturbance of fat metabolism, the liver appears to be unable to store injected dextrose as glycogen. De Fillipi showed that sugar is less well tolerated by a starving than by a well-fed dog, and lactose is better tolerated when given in milk than when taken alone. Cramer found also that the administration of lard along with sugar raises the limit of tolerance.[2]

Of the physiology of fat after reaching the blood stream little is known. Apparently it enters into some combination from which it cannot be extracted by ordinary solvents, the so-called "masking" of fat; but a direct combination with glucose has never been proved, although a compound of mannitol and a fatty acid has been synthesised in the laboratory.

Method of Experiment.

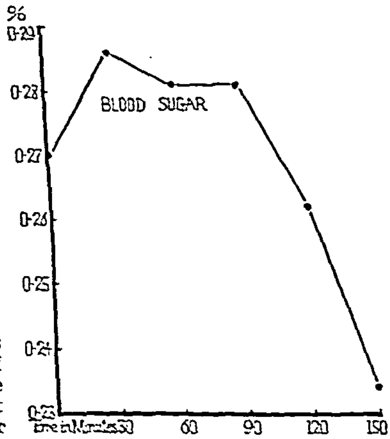
The following experiments were made with a view to investigating this relationship. The problem is difficult and did not appear to be one which could be attacked by animal experiments, as both fright and anæsthetics may raise the blood-sugar considerably. As Allen has shown that glucose given intravenously behaves differently from that absorbed from the intestine, oral administration only was resorted to, the experiments being made chiefly on ourselves so that the diet could be controlled as far as possible. The blood-sugar was estimated by Maclean's method and the blood-fat by Bloor's, both of which are sufficiently well known as to require no further mention here. It is noticeable that considerable variations were found in the amount of blood-fat in spite of prolonged fasting. Control experiments were made: in the estimation of blood-sugar the error was found to be negligible; in the estimation of blood-fat it was not greater than 5 per cent.

In a normal subject after 50 g. of glucose the blood-sugar curve rises to 0·17–0·2 and falls to normal or below in 60 to 90 minutes. As Maclean has pointed out, sugar is still being absorbed from the intestine at the end of that period, but apparently some mechanism has been brought into action which stores the sugar as soon as it has been assimilated, and, within limits, the rise of the blood-sugar curve appears to be independent of the nature or quantity of carbohydrate taken (except lævulose). We have noted that if an ounce of fat or alcohol be taken an hour before a dose of 50 g. of glucose, although there may be some delay in the beginning of the rise of the curve—presumably owing to a retarded passage through the stomach—yet once the rise has started it follows a normal curve, much as when glucose alone has been taken. It seems reasonable to deduce, therefore, that the blood-sugar curve should be regarded as an indication of the capacity for storage rather than as a measure of the rate of absorption from the intestine. Variation in the rate of absorption is, however, a source of error in all these experiments and is unavoidable, but as all were done on an empty stomach and were frequently repeated we believe it has been reduced to a minimum.

The Effect of Fat on Blood-Sugar.

If fat be taken there can usually be observed a marked fall in the blood-sugar. Fig. 1 shows the effect of 1 oz. of butter on a diabetic who had fasted for 12 hours previously. This fact has been observed by Cammidge and his co-workers[3] and has been confirmed by us on numerous occasions. There appear to be two possible explanations of this effect of fat on the blood-sugar: either there was increased use of sugar to oxidise the excess of fat in the blood, or some inhibitory mechanism has been brought into play, leading to an increased storage of carbohydrate.

FIG. 1.



Effect of 1 oz. of butter on the blood-sugar of a diabetic.

The Effect of Fat on Adrenalin Hyperglycæmia.

A hypodermic injection of 20 minims of adrenalin invariably produced a bigger rise of blood-sugar if fat had been taken previously, the subject and the diet on each occasion being identical. The longer the interval between the taking of the fat and the injection of adrenalin, the greater the rise. This was particularly noticeable after cod-liver oil, which is known to be absorbed more rapidly than any other form of fat. Table I. shows the results obtained.

These results appear to indicate an increased storage of carbohydrate after fat has been taken.

TABLE I.

		Maximum rise of blood-sugar.
(1)	No fat	0·16
(2)	„ „	0·159
(3)	75 c.cm. cod-liver oil 1 hour previously ..	0·164
(4)	75 „ olive „ 3 hours „ ..	0·21
(5)	75 „ „ „ 3 „ „ ..	0·198
(6)	75 „ cod-liver „ 3 „ „ ..	0·242

Three possible explanations suggested themselves to us to account for the increased storage: (*a*) The direct conversion of fat into carbohydrate; (*b*) the use of fat as a source of energy, thus sparing the carbohydrate stores; (*c*) some action of the fat on the storage of carbohydrate.

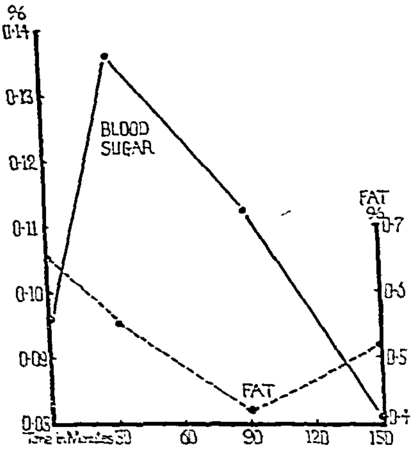
Of these the first seems improbable; even if so complicated a chemical reaction does occur, the time between the taking of the fat and the injection of adrenalin appears too short for the transformation to have taken place. In addition, the feeding of fat to a phloridzinised or depancreatised dog has been shown to produce no increase of glycosuria. With regard to the other explanations, both appear possible; the following experiments, however, seemed to show that the fat may take a more active part in the storage of carbohydrate.

The Effect of Sugar on Blood-Fat.

We have shown that fat diminished the sugar in the blood; we next investigated the effect of sugar on the blood-fat and found it produced a diminution of the latter. Sometimes the fat curve rose again after the sugar was absorbed (Fig. 2); occasionally it reached a higher point than when the experiment was commenced. Sometimes it produced a continuous fall of blood-fat. Table II. shows some of the results obtained after a dose of 50 g. of glucose. The experiments were done 7 to 18 hours after a meal, and as we found by control experiments that the blood-fat fell to normal after the sixth hour, there can be no question of absorption from the intestine. It was not a concentration effect, as the hæmoglobin remained constant throughout.

Excess of sugar, therefore, appears to have a considerable, if temporary, effect on the amount of extractable fat in the blood.

FIG. 2.



Effect of 50 g. of glucose on the blood-fat.

Effect of Calcium Salts.

By giving large doses of calcium salts (100 gr. of either the lactate or chloride) we were able temporarily to increase the acetone in the urine both in normal and diabetic subjects. Usually this was considerable, but occasionally it did not occur in certain of the more severe cases of diabetes. Allen and Wishart[4] were unable to find any increase of blood-fat on giving calcium salts to dogs. We found invariably, however, that calcium salts raised the blood-fat both in normal and diabetic persons. We were able to produce this after fasting for 18 hours; the effect, therefore, was not due to an increased absorption from the intestine. As the blood-sugar and hæmoglobin were not increased, this was not a concentration effect, nor did it appear to be due to an inhibition or oxidation of the fat by the blood-sugar, as if that were so one

TABLE II.

Subject.	Duration of fast before expt.	Commencement.	1 hr. later.	2 hrs. later.
	Hours.	Per cent.	Per cent.	Per cent.

A.H.	18	0·363	0·357	0·351
T.H.O. ..	18	0·416	0·375	0·233

would expect an accumulation of the latter. The increase of fat appears to be due either to a liberation of compound which had previously masked the fat, or to a mobilisation from the tissues. The association of a temporary lipæmia with an acetonuria after calcium salts seems to show that the latter is not due to an increase of the permeability of the kidney as we had at first supposed. Table III. gives some results.

If 50 g. of glucose be given three hours after 100 gr. of calcium the blood-sugar curve was found to be higher than normal, usually rising to 0·2 per cent. or over, and failing to return to the previous figure in 1½ hours; sometimes it had not become normal in two hours' time. We also found that if the blood-fat had been raised by a dose of calcium it was not lowered by 50 g. of glucose as in Table II. This suggests that the blood-fat had been altered in some manner, so interfering with the mechanism of storage. In a mild diabetic who had been free from sugar for over a year 100 gr. of calcium so altered his metabolism that he was unable to take any carbohydrate without becoming glycosuric, although previously he had been able to take 2 oz. of white bread daily with impunity. This condition was transient and returned to normal in a fortnight's time.

Calcium has been shown by Clowes to be intimately concerned with the surface-tension of fat and can convert an emulsion of fat in water into one of water in fat. A possible explanation of the above experiment is some alteration of the surface-tension of the blood-fat diminishing permeability into the tissues in much the same way as it is known to affect the permeability of the kidney.

The Effect of Fat on the Blood-sugar Curve.

If fat be taken in considerable quantities (75 c.cm. of cod-liver oil or olive oil) 4 to 12 hours before 50 g. of glucose, so that when the latter is given the blood is flooded with fat, or if the sugar be suspended in fat, a marked prolongation of the sugar-curve results; the rise is usually greater than normal, often up to 0·24 per cent., and this usually has failed to return to normal in two hours, assuming at times almost diabetic proportions. Excess of free fat in the blood, therefore, appears to interfere with the absorption of glucose by the tissues. We have repeated this experiment many times, as our results appear to be the direct opposite of those of Labbé and Theodoresco, who found that fat diminished the rise of the blood-sugar curve.[5] If, however, a large quantity of fat be taken 18 to 24 hours before the dose of glucose, thus allowing it to be assimilated into the tissues, this effect is not seen; on the contrary, we have noted a more rapid fall of the blood-sugar under these circumstances.

Discussion of Results.

Although the results obtained cannot be looked on as conclusive, and are probably affected to some extent by variation in the rate of absorption, the above evidence seems to show that the blood-sugar has a relation to the blood-fat, other than that of a mere oxidising agent. Fat properly absorbed into the tissues appears to increase the storage of carbohydrate; if not so absorbed, or if mobilised by calcium, the storage is interfered with. Possibly improper storage of the fat may account for the tendency of a high fat diet to produce glycosuria in some cases of diabetes.

It is noticeable that practically all conditions which lead to a hyperglycæmia lead to a lipæmia as well; this may be attributed to diminished oxidation. We have been able to produce a distinct rise of blood-fat in addition to a hyperglycæmia by the injection of adrenalin (from 0·48 to 0·56 per cent.); in this case, at least, it is difficult to understand why the liberation of a large amount of oxidising material should be accompanied by an increase of the substance to be oxidised. We suggest that a more probable explanation is that both were stored and liberated together, an explanation which recent work on the effect of insulin in diminishing lipæmia does much to confirm.[6]

In conclusion, we wish to express our thanks to Prof. Shaw Dunn for allowing these experiments to be conducted in his laboratory.

A SERIES OF CASES OF TUBERCULOSIS TREATED WITH SPAHLINGER'S VACCINE.

BY E. H. COLBECK, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, E.;

AND

S. ROODHOUSE GLOYNE, M.D. LEEDS, D.P.H.,
PATHOLOGIST TO THE HOSPITAL.

DURING the period 1913–14, the following cases were treated at Victoria Park, by means of the Spahlinger vaccine. (Cases 10 and 11 were treated with serum.) In each case the nature of the treatment was explained as far as possible to the patient or his relatives, and permission to use it obtained. One of us (E. H. C.) was responsible for the treatment, and the other (S. R. G.) for the laboratory examinations involved, whilst Mr. Spahlinger himself prepared the vaccines in his own laboratory. As far as we can ascertain, the following list comprises all the cases treated, with the exception of one, some sheets of whose record have been unfortunately mislaid. It was not a fatal case. On leaving Victoria Park, some of these patients had a further course of vaccine at Mr. Spahlinger's laboratory in London until October, 1914, but the records here given deal only with the period of their treatment in Victoria Park Hospital.

CASE 1.—J. W. A., aged 35, light meter maker. *Family history of tuberculosis.* History of cough for *last two winters*, hæmoptysis two months ago. *On admission*, 21/8/1913, there were signs of infiltration at *right apex* and left upper lobe; mild pyrexia, *small amount* of sputum, tubercle bacilli present; weight, 8 st. 10½ lb. Thirty-two injections given. On discharge, 17/1/1914, there were no active physical *signs*, temperature was normal, the last three *sputum examinations* were negative, and the weight 9 st. 3½ lb. In 1923 reported as well and at work since 1915.

CASE 2.—J. H. C., male, aged 30, furniture remover's porter. History of cough, hæmoptysis six years ago and again recently, and of loss of weight (1 st.); in-patient Brompton Hospital, 1909, later Mount Vernon, and South Mimms. On admission, 29/11/1913, signs of some re-activity of old lesions, but afebrile; weight, 10 st. 13½ lb. There was a small amount of sputum, tubercle bacilli found once in 19 examinations. Twenty-three injections given. On discharge, 9/4/1914, there were no signs of active disease, and weight was 11 st. ¼ lb. In 1923 reported as well and at work since 1915.

CASE 3.—C. D., male, aged 34, cook. Pulmonary tuberculosis first diagnosed in 1911; had lost 9 lb. in weight. *On admission, 4/8/1914, there were signs of infiltration of* right upper lobe and left apex, mild pyrexia; weight, 9 st. 10¼ lb. Sputum was scanty and contained tubercle bacilli. Had had *injections* of Spahlinger vaccine before admission. Five injections given at Victoria Park. On discharge, 3/10/1914, there were no signs of active disease, temperature was normal, sputum absent, and weight 10 st. 1 lb. In 1923 reported as well and as having been in active work since 1915.

CASE 4.—G. W. J. F., male, aged 37, general labourer. Father and one sister had died of tuberculosis. Had lost 23 lb. in weight. Had previously been an in-patient at Victoria Park in 1912, when he had 29 sputum examinations, only one of which was positive; transferred to sanatorium in 1913. On admission again, 27/5/1914, signs were chiefly bronchitic, with some infiltration of both lungs; there was mild pyrexia with scanty sputum, 17 examinations for tubercle bacilli being negative; weight, 9 st. 6½ lb.; dyspnœa on exertion, pain in chest, palpitation, giddiness, indigestion. Fifteen injections given. On discharge, 14/10/1914, there was no evidence of active disease beyond a few scattered rhonchi; temperature normal; weight, 9 st. 13¼ lb. Enlisted in army during war. At present time attending out-patient department as a pensioner; three examinations of sputum for tubercle bacilli have been negative. Reported as at work since war service.

CASE 5.—F. M. J., female, aged 34, post-office clerk. Father died of pulmonary tuberculosis. History of cough, general weakness, dyspnœa, night-sweats, loss of weight (1 st.). Hæmoptysis three months ago. On admission, 24/10/1913, she had tachycardia, pains in back, indigestion, and signs of infiltration of both upper apices and left base; no fever; a trace of sputum on one occasion only, when it contained no tubercle bacilli; weight, 6 st. 8 lb. Fourteen injections given. On discharge, 17/1/1914, moist sounds had cleared up and weight was 6 st. 8¾ lb. In 1923 *reported* as well and at work since 1914.

CASE 6.—J. E. P., female, aged 39, married. Father died of pulmonary tuberculosis. History of cough, dyspnœa, night-sweats, general weakness, and loss of weight (1 st.), six months' duration; hæmoptysis three months ago. On admission, 24/10/1913, she had pain in back, indigestion, tachycardia, and slight pyrexia, with signs of early infiltration of both apices and left base; a trace of sputum obtained on two occasions only, no tubercle bacilli present; weight, 7 st. 13 lb. Eleven injections were given. On discharge, 20/12/1913, there were no active signs in lungs and no pyrexia; weight, 8 st. 5 lb. In 1923 reported as well and at work since 1914.

CASE 7.—A. W., male, aged 49, hairdresser. History of cough for last seven years, with hæmoptysis three years ago, and recent loss of weight (10 lb.). Pulmonary tuberculosis first diagnosed in 1911, when he had treatment in a sanatorium. On admission, 22/9/1913, there were signs of infiltration of whole of right lung with excavation and disease of left upper lobe; laryngitis; afebrile; half an ounce of sputum daily, tubercle bacilli present; weight, 9 st. 6 lb. Thirty-two injections given. On discharge, 10/2/1914, chest almost dry, sputum very scanty, bacilli present on last examination a week before discharge; afebrile; weight, 9 st. 8 lb. In 1923 reported as well and at work since 1914.

CASE 8.—J. C. N., aged 40, chauffeur. History of cough, two to three months' duration, with loss of weight (6 lb.) and a streak of blood in sputum a fortnight before admission. Admitted 19/9/1913, with signs of infiltration of upper lobe, half an ounce of sputum daily, tubercle bacilli present; afebrile; weight, 9 st. 2 lb. Twenty-three injections given. On discharge, 15/1/1914, no moist sounds were found in lung, and last four sputum examinations showed no tubercle bacilli; afebrile; weight, 8 st. 11 lb.

CASE 9.—W. T., male, aged 37, engineer's labourer. History of chronic cough for some years, with loss of weight (9 lb.), tubercle bacilli reported to have been found in sputum by panel doctor and also whilst at sanatorium. On admission, 18/10/1913, there were signs at both apices and left base behind, but sputum was scanty, and no tubercle bacilli were present; afebrile; weight, 10 st. 5¾ lb. Fifteen injections given. On discharge, 14/1/1914, there were no signs of activity, still a trace of sputum, but nine examinations for bacilli had been negative; afebrile; weight, 10 st. 8½ lb. Reported as killed in France during the war.

CASE 10.—A. E. F., male, aged 37, brass-plate maker. History of cough, &c., 10 weeks' duration, and loss of weight (15 lb.). On admission, 20/10/1913, he had dyspnœa, general weakness, pain in chest, indigestion, and signs all over left side (? pleuritic) and at right upper lobe, with a trace of sputum but no tubercle bacilli; febrile; weight, 8 st. 2 lb. Eight injections (serum) given. On discharge, 28/2/1914, no moist sounds were heard in lung and 15 sputum examinations had been negative; afebrile; weight, 8 st. 12½ lb.

CASE 11.—F. E., female, aged 14. Father and mother died of tuberculosis. History of enlarged glands of neck since three years of age. On admission, 31/10/1913, there were enlarged hard glands on left side of neck, one of them showing signs of breaking down; no signs in lungs, and the trace of sputum obtained on four occasions showed no bacilli; afebrile; weight, 5 st. 2 lb. Eleven injections (serum) given, followed by three more after an interval of rest. On discharge, 1/4/1914, glands had subsided and weight increased to 5 st. 11 lb.

CASE 12.—J. P., male, aged 18, hairdresser. History of cough, &c., two years' duration. On admission, 27/1/1914, there were signs of infiltration of whole of right lung and left apex; sputum scanty, bacilli present; afebrile; weight, 8 st. 13¼ lb. Twenty injections given. On discharge, 20/7/1914, there were still moist sounds in right lung with scanty sputum, and bacilli present; afebrile; weight, 9 st. 8½ lb. Readmitted with stained sputum and tubercle bacilli present, 3/4/1917, but discharged at own request a fortnight later and joined the army. Readmitted again in 1922 and died. Autopsy refused by relatives.

CASE 13.—H. P., male, aged 25, railway clerk. History of cough eight months' duration. On admission, 11/8/1914, there were signs of infiltration of both apices with scanty sputum, tubercle bacilli present; febrile; weight, 9 st. 10 lb. Only four injections given; Spahlinger's vaccine treatment then stopped, owing to outbreak of war. On discharge, 7/6/1915, no moist sounds were heard, tubercle bacilli were still present; afebrile; weight, 10 st. 3¾ lb.; transferred to sanatorium.

CASE 14.—E. F., male, aged 34, schoolmaster. Two brothers died of pulmonary tuberculosis. History of cough, &c., two and a half years' duration, loss of weight, and hæmoptysis. On admission, 25/5/1914, there were signs of infiltration of right upper lobe and left apex; sputum scanty, bacilli present; weight, 12 st. 10 lb. Sixteen injections given. On discharge, 17/9/1914, the lungs were practically dry, sputum scanty, bacilli present; weight, 12 st. 12 lb. Patient reported himself as well and at work in 1916 and again in 1917. In 1923 reported as not traced.

CASE 15.—J. H., male, aged 32, joiner. An advanced case who came over from Paris specially to try the treatment. Three years' history. On admission, 19/5/1914, there were extensive signs in both lungs, with three to four ounces of sputum daily and tubercle bacilli present in large numbers; irregular pyrexia; weight, 8 st. 4¼ lb. As no Spahlinger serum was then available and patient was considered too advanced for vaccine treatment, eight injections of lipoids (lecithin, &c.) prepared by Mr. Spahlinger, were given. Patient got steadily worse, and died 16/7/1914. Autopsy could not be obtained.

CASE 16.—C. N., male, aged 22, student. History of pleurisy a year ago. On admission, 15/7/1914, there were signs of fibrosis of whole of left lung and recent infiltration of right apex; sputum scanty, bacilli present; febrile; weight, 10 st. 6¾ lb. Nine injections given, and Spahlinger treatment then stopped owing to outbreak of war. Subsequently an autogenous streptoccocal (from sputum) vaccine given. On discharge, 9/2/1915, signs in lungs had not markedly altered, but sputum contained no tubercle bacilli; still febrile; weight, 10 st. 6 lb.

CASE 17.—A. W. T., male, aged 34, groom. History of cough, hæmoptysis, &c., for the last ten weeks. On admission, 1/12/1913, there were signs of infiltration of right upper lobe, with excavations at apex and infiltration at *left hilus*; slight pyrexia; *sputum* scanty, tubercle bacilli present; weight, 9 st. 9 lb. On discharge, 30/6/1914, no moist sounds were heard; afebrile. In 1920 reported as well and at work, and in 1923 as not traced.

In fairness to Mr. Spahlinger we would point out that the cases were treated during the early stages of his research, and that the work was interrupted by the war. We have refrained from making any comments on the cases.

ACUTE *BACILLUS COLI* INFECTION OF THE GASTRO-INTESTINAL TRACT

IN A NEW-BORN BABY, CONTRACTED FROM ITS MOTHER.

BY REGINALD C. JEWESBURY, M.D. OXF.,
F.R.C.P. LOND.,
PHYSICIAN TO THE CHILDREN'S DEPARTMENT, ST. THOMAS'S HOSPITAL; MEDICAL DIRECTOR, THE MOTHERCRAFT TRAINING SOCIETY, LONDON;

AND

LEONARD S. DUDGEON, C.M.G., C.B.E.,
F.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LONDON; DIRECTOR OF PATHOLOGY, ST. THOMAS'S HOSPITAL.

THERE are very few records of fully investigated cases of acute gastro-intestinal infection in the new-born contracted from the mother at birth detailed in the literature. Julius Hess[1] states that streptococcal infection of the infant may occur through the maternal circulation, or secondarily through the mother's milk, lochia, or other infected material reaching the gastro-intestinal tract of the baby. Infections of the intestinal tract due to dysentery, typhoid, and paratyphoid bacilli are seldom seen during the first few days of life unless the mother is infected, but colon infections are not so uncommon. Nauwerk and Flinzer[2] quoted by Ritter von Reuss, refer to the case of a child who died on the second day after birth from melæna. *B. paratyphosus* B was isolated and was agglutinated by the mother's blood. The mother, a few weeks before delivery, had suffered from severe diarrhœa. These authors also suggest that during birth infection of the child may occur from bacteria present in the mother's vagina, or that infected lochia may be swallowed by the child and cause an infection of the intestinal tract.

As we possess the full records of the illness of a child from birth up to and including the period of convalescence, we have considered it advisable to place our observations on record so that this method of infection of the child may be fully considered in the future. The mother in this case had suffered from an infection of the urinary tract due to a colon bacillus which had caused acute symptoms with high temperature and the usual associated clinical phenomena on two occasions during the antenatal period.

It may be advantageous here to refer briefly to the work of Dudgeon, Wordley, and Bawtree[3] on *B. coli* infections of the urinary tract. They have divided these infections into hæmolytic and non-hæmolytic, and further subdivided the two groups with agglutinating antisera. They have shown further that in colon infections of the urinary tract it may be possible to isolate the causative organism from the intestinal tract. In their experience, the most severe urinary infections are caused more commonly by hæmolytic strains, and the infections caused by hæmolytic colon bacilli are more common in the male sex. The commonest hæmolytic strain in coli infections of the urinary tract is that labelled by them as "Dow," and this is the responsible organism in the case about to be described in detail.

Clinical History.—Female child; full term; labour normal. Birth weight 8 lb. Breast-fed from birth, at four-hourly intervals; five feeds. The third day after birth the baby became very restless and began to vomit. The vomiting occurred during feeds and in the intervals, on the average three to four times daily. Test weighing showed that it received 21 oz. of milk on the fifth day. From the sixth day it was fed on expressed breast milk diluted one-third, so that the total amount of milk allowed was 15 oz Normal meconium was passed at the outset, but on the fifth day mucus began to be present in the stools. The child was first seen by one of us (R. C. J.) on the ninth day; she was then very restless, the limbs were rigid, colour was greyish. She was passing thick tenacious mucus, vomiting mucus, and had three septic fingers. Temp. 99° F. Weight, 7 lb. 3 oz.

Treatment.—Treatment was commenced by giving 1 drachm each of castor and olive oils. She was fed on expressed breast milk, boiled for four minutes and diluted one-fourth with water. On the twelfth day the condition was worse; the greyish colour was more marked; vomiting was more frequent and much more mucus was passed per rectum; the weight had fallen to 7 lb. Rectal irrigation was ordered with a solution of bicarbonate of soda followed by normal saline. During the next few days the amount of mucus passed in the stools was excessive; restlessness was very pronounced; there was evidence of severe abdominal discomfort, and the fingers were still septic. Rectal lavage caused the evacuation of considerable quantities of mucus, together with milk curds. The temperature varied from 97°–99°. Some septic spots now appeared on the back. Castor oil was given at repeated intervals, and syrup of dimol, 15 minims, three times daily. The weight fell to 6 lb. 14 oz. on the seventeenth day.

Course of Condition.—On the twenty-fifth day feeding with breast milk had to be discontinued owing to the mother's condition, as in addition to a colon infection she was suffering from organic heart disease. The child was then fed on a modified unsweetened condensed milk mixture giving percentages of sugar 5·7, fat 1·4, protein 1·4. The caloric value of the food was 216 against a theoretical caloric requirement of 350. The sugar (dextri-maltose) was gradually raised to 7 per cent., but the fat was kept low owing to a marked inability to digest fat. By the thirty-fifth day the child was taking sufficient food to yield its theoretical caloric requirement—i.e., 350 cals. Mucus continued to be passed at intervals but became much less; the septic lesions healed and the colour improved. Orange juice was later introduced into the diet. Small vomits continued after feeds, and in some of these mucus was present. The weight showed a steady increase. From the thirty-second day the diet was gradually changed to a fresh cows' milk mixture, giving percentages of sugar 6·9, fat 2·7, protein 1·5. It was not until the sixty-ninth day after birth that the mucus had disappeared from the stools on naked-eye examination, and these now became normal for the first time. After this time the vomits were less frequent, but they still contained small quantities of mucus at intervals. The cows' milk mixture was continued, but it was still found necessary to keep the fat down to 2·7 per cent. (a 50 per cent. crude cod-liver oil emulsion was used to adjust the fat).

The child now (18 weeks) appears to be in better health; the stools are normal, but there are still occasional vomits with mucus, and the last sample of mucus examined (at 16 weeks) showed the presence of the same strain of *Bacillus coli* in abundance. The temperature varies between 98° and 99°. The urine (at 18 weeks) contained bacilli, but no pus, and the bacillus proved to be the same strain of *Bacillus coli* as found elsewhere.

Bacteriological Examination of Mother.

Urine.—Very turbid; pus, masses of Gram-negative bacilli, and traces of sugar present. A pure culture was obtained of an actively hæmolytic colon bacillus.

Lochia.—Leucocytes abundant and Gram-negative bacilli; pure culture obtained of an actively hæmolytic colon bacillus. Breast milk: First examination made 11 days after the birth of the child; some polymorphs present, but no bacteria seen; epithelial cells numerous, both those containing fat droplets and fat-free cells. Free fat and degenerated cells abundant. A considerable growth was obtained of a non-hæmolytic Gram-positive short-chained strepto-diplococcus, which formed acid in mannite, lactose, and salicin, firmly clotted milk, but inulin was unaffected. The milk was re-examined a week later; streptococci were present but relatively scarce, but the *Staphylococcus albus* was abundant. Colon bacilli were not cultivated on either occasion.

Blood.—Examination made 18 days after the confinement. Red cells, 4,260,000 c.mm.; hæmoglobin, 72 per cent.; colour index, 0·8; leucocytes, 6720 per c.mm.; polymorphs, 71 per cent.; eosins. 6 per cent.

Blood Serum.—The blood serum gave an end-point agglutination with the typhoid antigen of 1 in 100, 1 in 25 with paratyphoid A, but no reaction with B or C (inoculation).

Bacillus Coli Reactions.—Several strains were employed as antigens, but the only positive reaction occurred with the standard hæmolytic urinary antigen "Dow" which is similar to the organism infecting both mother and child. A complete reaction occurred with a dilution of 1 in 100. incomplete 1 in 400, and the end-point of the reaction was 1 in 1000. The serum was also tested for the precipitin reaction with the same strain of colon bacillus. The filtered antigen employed by Dudgeon, Wordley, and Bawtree[3] was used. A positive reaction occurred with dilutions of 1 in 5, 10, 20, 40, and 80.

Bacteriological Examination of Infant.

Fæces.—Mucus present in great abundance; well-marked bile reaction obtained; blood present and masses of both leucocytes and epithelial cells. Fats and soaps also present.

A very heavy growth was obtained of the hæmolytic bacillus coli, and of a non-hæmolytic streptococcus. These were the only bacteria present on blood-agar plates after the motion had been dried on tiles as introduced by Dudgeon for the routine bacteriological examination of the fæces.[3] [4] The streptococcus present in the fæces of the baby was morphologically and culturally similar to the streptococcus which had grown so abundantly in the mother's milk, and in both instances was non-hæmolytic. The *B. coli*, which was actively hæmolytic in solid and liquid media, was similar in every detail with the strains isolated from the mother. A second examination of the baby's fæces was made 14 days later. They were now semi-solid, and only traces of mucus were present. Hæmolytic colon bacilli were present, but relatively scanty as compared with the previous records. Numerous colonies of hæmolytic *Staphylococcus aureus* and *albus* were obtained and of non-hæmolytic streptococci. The urine was normal, but during convalescence the infant developed a bacilluria, due to the same strain of colon bacillus.

Vomit.—The thick mucus vomited by the baby was examined. Bacilli were found to be numerous, and an abundant growth of hæmolytic colon bacilli and non-hæmolytic streptococci were obtained. On re-examination one week later colon bacilli were not cultivated, but were isolated at a later period.

Colon Bacilli.—The same strain of colon bacilli was isolated from the urine and lochia of the mother, and from the intestinal mucus, gastric contents, and urine of the infant. The colonies formed abundance of acid and gas in lactose and mannitol, rapidly clotted milk, gave a marked indol reaction, and did not liquefy gelatin. Saccharose was rendered alkaline, while acid and gas was formed in dulcitol, but this medium subsequently became alkaline. These colon strains were very actively hæmolytic on blood-agar, and in 0·5 per cent. and 0·85 per cent. sodium chloride in peptone water to which 0·1 c.cm. of human red cells was added. The hæmolytic action was of equal intensity in both the stages detailed by Dudgeon, Wordley, and Bawtree.[3]

Serological Results.—The bacilli isolated from the various sources referred to were subcultured on ten successive occasions in veal broth and tested with the various colon anti-sera derived from hæmolytic and non-hæmolytic strains referred to by the above-mentioned investigators. The anti-serum made from the commonest hæmolytic colon strain known as "Dow" reacted to full titre with these cultures. The end-point of 1 in 20,000 was reached, which is the limit of reaction between the anti-serum and its own antigen. It was also shown that the blood of the mother reacted with this antigen to the extent of $\frac{1000}{20000}$, which is a very strong colon agglutination reaction for a human serum.

Harvey Cushing and Livingood[5] published a most interesting and valuable contribution to the bacteriology of the alimentary canal in the Johns Hopkins Hospital Reports in 1900. The intestinal flora are grouped into the obligatory or permanent intestinal bacteria, and the transient which are introduced with the food and persist only when a suitable pathological process is present in the intestinal mucosa or when they are the cause of such a condition. Cushing and Livingood refer to the original work on human sucklings by Escherich in 1885 and 1886, where he showed that *B. lactis aerogenes* is the obligatory form which is present high up in the digestive tract, while *B. coli* flourishes lower down. The essential fact, however, that these bacteria which are not present in the meconium at birth must enter with the food, swallowed air, or during bathing of the infant, is discussed. In our case the colon bacillus was present in pure culture in the stomach mucus, as well as in that passed per rectum, and the organism known as the *B. lactis aerogenes* was not isolated. Todd[4] examined 101 specimens of normal fæces from 91 healthy children under 1 year of age. The stools were examined bacteriologically by Dudgeon's method referred to in detail by Todd and Wordley.[6] Hæmolytic colon bacilli were obtained in 12 cases, and in eight of the number the ages of the babies, which were breast-fed, varied from 2 to 19 days. It is important, however, to contrast the findings in our case, in which the colon bacilli cultivated at the commencement of the illness were all hæmolytic and were present in great abundance, with the findings in Todd's cases, where hæmolytic colonies were present, but only in limited numbers. Of the eight strains isolated by him, six were agglutinated by the colon anti-serum (hæmolytic type "Dow") which is the same anti-serum as we employed.

Discussion.

At the present time, while world-wide attention is devoted to the subject of infant welfare and the causes of infant mortality, it is of the utmost importance to realise that various infective conditions may occur at the ante- and post-natal periods and at the short interval during the birth of the child. It is to this intermediate or intra-natal stage that this case which we have described in detail belongs. In this instance the mother was infected with a certain strain of *B. coli* which had produced two attacks of acute coli fever. The urine contained a large amount of pus and masses of bacilli, and the lochia also were similarly infected. In our opinion, the baby was infected at birth by swallowing the urine or lochia in which the organism was present in abundance. There is very little information to be obtained from the literature of this method of infection, although some continental and American writers refer to it. The possibility of the child being infected during the ante-natal period with this organism must also be considered, as it is known to occur in typhoid and paratyphoid fevers from infection in the mother. Our view that the infection occurred at birth is supported by the fact that the illness commenced about three days after birth, and the condition of the child at birth was perfectly satisfactory. The illness commenced and continued with gastro-intestinal symptoms and associated clinical phenomena. The child passed thick mucus by the bowel for some weeks and also vomited mucus. The causative organism was present in the intestinal mucus for many weeks, and 18 weeks from the onset of the illness it was present in the vomited material during a gastro-intestinal upset. At this period the urine was found to show a bacilluria due to the same organism. The illness was so severe that it nearly cost the life of the child, and improvement only occurred after many weeks of most careful nursing and treatment. It was thought that the mother's milk might also be infected with the colon bacillus, partly because of the general infection from which she had suffered, but also owing to information obtained by us from our investigations on the bacteriology of human milk which are now in progress. Repeated examination, however, failed to confirm this suspicion. It is possible from the available evidence that the heavy streptococcal infection of the mother's milk may have assisted in the causation of the gastro-intestinal infection in the infant.

In the case of breast-fed infants, a gastro-enteritis is very frequently caused by over-feeding, but when the amount of breast milk is proved by test weighing to be *not* in excess, and the enteritis continues with loss of weight, the case we have reported indicates the necessity for: (1) A bacteriological investigation of the breast milk, as well as a chemical examination; (2) a bacteriological examination of the stools and vomit of the child.

Further, when dealing with women known to have a coli infection, it would appear wise to take special care to cleanse the mouth of the child as soon as possible after birth with some non-irritant antiseptic solution, in a similar manner to which the eyes are treated with silver nitrate solution when a gonococcal infection in the mother is present.

A CASE OF
QUINTUPLE PREGNANCY.

BY S. R. FOSTER, *M.C.*, M.B., B.CH., B.A.O. BELF.,
ASSISTANT VISITING SURGEON, BELFAST MATERNITY HOSPITAL;
AND
WILLIAM CARSON, M.B., B.CH., B.A.O. BELF.,
RESIDENT SURGEON TO THE HOSPITAL.

IN 1904 Prof. Nijhoff[1] of Groningen (Netherlands) published the notes of a case of quintuplets which occurred in the practice of his friend, Dr. De Blécourt. With De Blécourt[2] he collected from the obstetrical literature, from 1694 to 1900, 28 additional cases. These they published the same year in book form. Further cases were recorded by Bernheim[3] in 1904, Martin[4] in 1917, and Hehir[5] in 1922. We have not been able to procure a copy of De Blécourt's and Nijhoff's monograph, but in the four cases above quoted the children were all well formed, although immature, and in three cases at least they died in a few hours or days. In the case reported by Sir P. Hehir, the children were stated to be of quite large size and doing well the day following birth. To date, therefore, it appears that 32 cases of quintuple pregnancy have been recorded.

The case which we now report differs from those already quoted in that two of the five fœtuses were monsters. One was anencephalic, and the other a small monstrous embryo only 3 cm. long.

History.—The patient, a multipara aged 33, had been married 11 years, and pregnant four times. Her first pregnancy terminated in a full-term normal labour ten years ago, and the child is still alive and healthy. Five years later she had a second uneventful normal labour, child alive and well. On May 19th, 1921, she aborted a two months fœtus and the uterus was curetted. Following the curette, she developed an abscess in the uterine wall, which subsequently burst into the peritoneal cavity. The patient had a perilous time, but was able to leave hospital in five weeks.

Her fourth pregnancy is the one under consideration. Her last menstruation ceased on May 26th, 1922. She was first seen at the beginning of October (by S. R. F.), wasted, anæmic, and slightly jaundiced. The uterus reached to just below the umbilicus. No fœtal parts could be felt, the patient said she had not felt movements, and no fœtal heart could be heard. Other signs of pregnancy were present, however, and on bi-manual examination the abdominal tumour was undoubtedly the uterus. It was felt certain, therefore, that the patient had within her uterus a product of conception.

Admission to Hospital.—Although the vomiting ceased the patient continued to lose flesh and appetite. She was admitted into hospital on Nov. 2nd, 1922. The uterus had now reached to three fingers-breadth above the umbilicus, but still no fœtal parts could be felt and no fœtal heart heard. The patient was very thin and slightly jaundiced. An examination of the urine proved negative. It was decided to empty the uterus. The cervix was dilated up to No. 12 Hegar, and a small rubber hydrostatic balloon was inserted into the lower uterine segment. After remaining in for 24 hours without labour resulting, it was removed and on the 5th the lower uterine segment was plugged with gauze.

Delivery.—During the night the patient had labour pains, but they were weak, occurred only at long intervals, and finally ceased altogether at 6 A.M. Mr. Thomas Holmes examined the case, and at 11 A.M. on the 6th the patient was anæsthetised. After removal of the gauze the os was found to be almost completely dilated and a bag of membranes presenting. The membranes were ruptured, a pair of feet brought down, and a small fœtus extracted. Another bag of membranes presented and was ruptured, and another fœtus extracted by the breech. Two others followed in exactly the same way. Rather sharp hæmorrhage now occurred, and the placenta was removed manually. It was very adherent and unfortunately damaged a good deal in its removal. Attached to the placental mass by a long thin cord a small smooth body was noticed and preserved; it proved to be a monstrous embryo. The four children were all immature, alive when born, but all died within half an hour. All were females, three were perfectly formed, one was an anencephalic monster. Their lengths and weights are as follows: (1) 29 cm., 15¼ oz.; (2) 30 cm., 15½ oz.; (3) 28 cm., 13¾ oz.; (4) 23 cm., 9¾ oz. (anencephalic).

The fifth fœtus was entrusted to Dr. Thomas Walmsley, professor of anatomy in the University of Belfast, who stained and sectioned it, and reported it as being a small monstrous mass measuring 3 cm. in length. "Attached to about the centre part of its anterior surface there was a delicate umbilical cord which contained, as demonstrated on microscopic section, small thin walled blood-vessels. The embryonic mass itself, on section, was found to consist of a surface covering of well-differentiated ectoderm, in which skin glands were definitely formed. Within the ectoderm the tissue mass was of the undifferentiated round cell type, a small amount of pre-cartilaginous tissue in the head region being the only definitive formation which could be recognised. There is no doubt, of course, of the embryonic nature of the rudiment."

The placenta weighed 15¾ oz. It was much damaged, but four separate amniotic sacs could be pieced together. The chorion could not be traced with any certainty. Five umbilical cords were attached to the placenta. Four were of ordinary size and corresponded to the formed fœtuses; the fifth, attached to the small monster, was only 1 mm. in diameter and 4½ in. long.

The patient had a normal puerperium, and left hospital in 14 days much improved. Two months later she had regained her lost weight and was looking and feeling quite well. With regard to the family history, a sister of the patient has had one pair of twins, and the wife of a brother has also had twins once. Otherwise the family history is negative.

Our thanks are due to Prof. Walmsley for the preparation of the sections, to the librarian of the Royal Society of Medicine for the loan of papers, and to Mr. T. Holmes for permission to publish the case.

Medical Societies.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE eighty-second annual meeting of the Association was held at the rooms of the Medical Society of London and the Royal Society of Medicine from July 9th to 13th, under the presidency of Lieut.-Colonel E. GOODALL (Cardiff Mental Hospital).

Sir Fredk. Willis, Sir Arthur Rose, and Dr. Havelock Ellis were unanimously elected honorary members of the Association. Dr. J. Carswell was appointed Maudsley Lecturer for 1924.

Dr. J. G. PORTER PHILLIPS (resident physician, Bethlem Hospital) read a paper on

Early Treatment of Mental Disorder,

really a survey of the out-patient practice of that institution. He said that in its early stage mental disorder might often permit the individual to adjust himself to his surroundings and follow his avocation without ever deserving the label "insanity." The exacting nature of life was chiefly felt by those with a weak or unstable mental make-up. Latterly several specialised clinics had sprung up to deal with early treatment of mental disorder. The out-patient department at Bethlem Hospital was inaugurated in 1919, and in 1922 the Maudsley Hospital commenced the indoor and outdoor treatment of civilians. The most hopeful results were to be looked for in cases in which mental and physical collapse was only partial and there was a good history. On the economic side of the question he pointed out that the cost per patient in out-patient treatment was about one-tenth that of a resident patient in a county mental hospital. Early treatment not only avoided much domestic misery and exhaustion of other members of the family; it also afforded good opportunities for research, whose results would greatly benefit mankind. At the Bethlem Hospital clinic 323 new cases were seen during the year. Dr. Phillips emphasised the great importance of the social side of this work carried on by the almoner and inquiry officer, who made careful and tactful inquiries into the home life and general conditions of the patients. He reviewed the provisions of the new Mental Treatment Bill, which he regarded as a stride forward in State medicine, remarking that the secret of modern progress often lay in propaganda.

The Relation of Chronic Sepsis to Mental Disorders.

This was the title of a very exhaustive paper by Dr. Henry Cotton, lecturer in psycho-pathology at Princeton (U.S.A.) University. He first paid a tribute to the part played by Dr. William Hunter in 1900, in drawing attention to the rôle of chronic sepsis in medicine; also to the work of Dr. Chalmers Watson.[1] In 1905 Dr. Cotton, working under Alzheimer at the psychiatric clinic in Munich, found distinct changes in the nerve cells in so-called functional disorders. Alzheimer regarded these changes as very significant. This shifted the conception of these disorders, which were previously considered to be primarily diseases of the mind and not of the brain. The former view was not logical, as abnormal structure seemed a necessary condition for abnormal functioning. He set himself to determine the cause of the associated fatty degeneration of the cortical nerve cells in the functional psychoses. A five years' study of disturbances of the endocrine system gave no decisive result, and gland therapy was a failure. In 1918, following the work of Hastings and King, they began to eradicate all foci of chronic sepsis from their patients, and the reward was an increase in the recovery-rate from 37 per cent. to 85 per cent. in the first year. Attention to the genito-urinary system was an important part of this work, and in some enucleation of the vesicles was necessary. It was not claimed that this work had solved the problem of mental disorders, but it had shown that disease of the brain tissue was the fundamental condition. The success of this work was based on the utilisation of all the methods developed in the field of general medicine, and especially that of chronic sepsis. Heredity, he thought, should not occupy the important place it had been assigned in the past: it was an idea which had been an obstacle to advance. He also thought that many of the extravagant claims made by psycho-analysts were unjustified, and Freudism had been a great handicap to psychiatry. He did not minimise the importance of the psychogenic factors in the causation of the psychoses, but regarded them as precipitative rather than causative, for in some cases psychosis developed without such factors being present. He proceeded to establish the thesis that chronic sepsis was a large and very important determining factor in mental disorders, and that these psychotic patients harboured multiple foci of infection. Hence he regarded the psychosis as a symptom—sometimes a terminal symptom—rather than as a disease entity. The paper contained a detailed reference to the foci found, and their micrococcal inhabitants. He was able to return 82 per cent. of the discharges as recoveries; and a successful treatment of 1412 cases in four years.

A discussion followed, in which Dr. W. Hunter, Dr. Chalmers Watson, Dr. T. C. Graves, and others took part.

Dr. Clement Lovell (pathologist at Bethlem Hospital) read a paper on the

Surface Tension of the Serum in Anxiety Psychoses.

He said no relation had been traced between the disappearance of blood-sugar and the alteration of the surface tension: but by dialysing heated and unheated specimens against distilled water he found a difference in the union of electrolyte and protein in the normal person and the anxiety case. In anxiety cases he found there was increased nucleation of the interlobular connective tissue of the pancreas. If the theory he advanced was true, a large number of the anxiety cases were due to a disordered endocrine balance, in which the pancreas was primarily at fault. Hence the treatment should be aimed at stimulating the pancreas, and vaccine methods directed to inflammatory conditions.

Dr. R. M. Stewart read a paper entitled

General Paralysis: Its Unsolved Problems.

Among the questions he propounded were the following: Was the *Spirochæta pallida* alone responsible for the genesis of general paralysis? When and how did it gain access to the nervous system? Was there a special strain of it in these cases? Or must the individual resistance of the infected person be considered as the deciding factor in the development of the disease? What was the meaning of the long latent interval before the onset of symptoms? Why did the cerebro-spinal fluid contain no organisms at a time when the brain contained millions? Why did not tabes, general paralysis, and optic atrophy occur in conjunction more frequently? Why did arsenical compounds fail to cure? He devoted his paper to a consideration of two problems: (1) the time of invasion of the nervous system in general paralysis; (2) the existence of special neurotropic strains of the *Spirochæta pallida*. General paralysis of the insane seldom occurred less than six to ten years after syphilitic infection; in tabes the period was usually longer. It seemed probable that the spirochætes circulating in the blood-stream gained access to the brain or its membranes during the time of general dissemination, and lay dormant until there occurred a favourable opportunity for their multiplication. This view was supported by the biochemical and other changes in the cerebro-spinal fluid. If the spinal fluid and the nervous system showed changes in from 30 to 40 per cent. of all cases of syphilis, why did general paralysis develop in only about 5 per cent. of infected persons? Two explanations could be offered: the organisms which attacked the nervous system might do so because they possessed a special neurotropic action; or the disease might make its appearance because the patient possessed a neuropathic disposition. These he considered in some detail, pointing out peculiar racial features in regard to the incidence of general paralysis of the insane. H. Noguchi had found that the incubation period of thicker forms of spirochæte was long and the lesions nodular, hard and sharply defined; with the thinner and more active types, large diffuse lesions were produced. It seemed that deficient early treatment of syphilis was a determining factor in the onset of general paralysis later in life.

Histological Examination of Pituitary Body.

Sir Frederick Mott and Dr. Ida M. D. Robertson contributed an instructive analysis of 110 cases in which the pituitary body of patients dying in asylums and hospitals was histologically examined, the work having been done by Dr. Robertson and verified by Sir Frederick Mott.

The summary of the conclusions was as follows: The cases of tuberculosis showed a certain amount of exhaustion, as evidenced by the breaking up of the cytoplasm of the eosinophil cells, the increase of the chromophobes, and the increased number of nuclei. The intracellular lipoid was also decreased. In general paralysis the lipoid content, in both cells and interstitial tissue, was increased. Cases of dementia præcox showed a marked degree of exhaustion, to almost complete atrophy of the cellular elements of the gland. The distinguishing feature of this, as compared with tuberculosis, was a deficiency of the nuclear chromatin. The association of tuberculosis with dementia præcox, especially with the advanced stages, was very marked, but in one of the most definite cases tuberculosis was not present. With regard to other psychoses, there was, normally, a considerable similarity in structure and staining reactions of the eosinophil cells of the pituitary gland to the interstitial cells of the testes.

Dr. T. Beaton (Bethlem Hospital) contributed an elaborate paper on the

Psychogenic Factor in the Causation of Mental Disorder.

He said that there were two main views of insanity according to whether the causal factors accepted were psychogenic or physiogenic. The issue between these had been unnecessarily complicated by the persistence of the old argument of body against mind. These must not be regarded as separate and opposed, but complemental. He agreed with McDougall that the dominating partner in the trinity of cognition, affection, and conation was conation; that was the thread of purpose throughout the life-history of the organism which bound the successive phases of experience together. He insisted that the psychological description of mental phenomena must have a correlation in nervous function.

---

[1] THE LANCET, 1922, ii., 127, 231.

Basal Metabolism in Mental Disorders and the Influence on it of the Diathermic Current.

Dr. JAMES WALKER (Cardiff Mental Hospital) read a paper with this title, paying special attention to dementia præcox. Mental and nervous symptoms occurred, he said, as a result of disease of the thyroid gland, but medication with the extract of that gland should only be employed where thyroid hypofunction was considered to be either a causative or a contributory factor. Several cases of dementia præcox he had shown to exhibit vagotonia—i.e., a subnormal body temperature, a tendency to bradycardia, and respiratory arrhythmia. In one or two of these cases examined during remission he had found an improvement in the basal metabolism and a disappearance of the vagotonic symptoms, showing that the oxidation deficiency in the cells was not a permanent condition. Psychic excitement profoundly affected metabolism, and produced a temporary increase in the sugar content of the blood. The most reliable information was yielded by patients in the stupor class, though these need not necessarily be cases of dementia præcox. He did not think the lowered metabolism was due to a diminution of the thyroid principle or autocoid, but to a decrease in all the bodily functions. With regard to treatment, the heat produced by the high-frequency current was endogenous—i.e., produced in the deeper-lying tissues. It produced a slight fall in the systolic blood pressure, an increase in the leucocytes, in the urine, and in the output of urea and ammonia nitrogen. The current produced, in 20 observed cases of mental disorder, an increase of 10 to 15 per cent. in the basal metabolism, 2 to 3 degrees increase in body temperature, and 20 to 30 beats per minute increase in the pulse. His conclusion was that diathermy was a useful therapeutic measure and one likely to play a definite part in furthering recovery. During remission in dementia præcox the basal metabolism approached that of the normal person.

Diagnosis of Dysenteric Infections in Mental Hospitals.

This subject was dealt with in an able paper by Dr. A. A. W. PETRIE, of the Maudsley Hospital. He said the diagnosis of acute cases was comparatively easy; the difficulty lay in the recognition of very mild chronic and latent cases. He first alluded to the causes of non-dysenteric diarrhœa, including tuberculous and nervous mucous colitis, and ulcerative colitis. With regard to the true dysenteries, the tropical dysentery due to the *Balantidium coli* could be excluded as it practically never occurred in mental hospitals. An investigation of asylum subjects showed 9·7 per cent. to be infected with the *Entamœba histolytica*, compared with 4 per cent. to 8 per cent. in the general population. He entered minutely into the differential characters, remarking that the principal bacilli occurring in bacillary dysentery were the Shiga bacillus and the Flexner bacillus, the former usually causing the more severe types of the disease, but the Flexner being the more common organism in asylum dysentery. In the chronic disease, help could be obtained from the agglutinins occurring in the blood.

The Ranchi European Mental Hospital, India.

The PRESIDENT read to the meeting a paper descriptive of the Ranchi Mental Hospital, contributed by Major OWEN BERKELEY-HILL, its medical officer-in-charge. This is the only mental hospital in India intended solely for the treatment of persons of either European or American parentage. The hospital is built on the "pavilion" system, and covers 85 acres, with ten wards, which will accommodate 92 male and 88 female patients. There is a nurse to every two or three patients and the general health is very good. The methods of life and treatment are detailed in the paper in a very interesting fashion.

In addition to other excursions, members visited the Maudsley Hospital, where Dr. EDWARD MAPOTHER explained the work being done there and gave some demonstrations in the laboratory.

ANNUAL DINNER OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—The annual dinner was held at the Hotel Metropole, London, on July 11th, Dr. Edwin Goodall presiding. Dr. Percy Smith, who proposed "The Legislature," gave an interesting sketch of the history of legal restraint in relation to the safety of person and property. The Bill now before Parliament for the admission of patients to county and borough mental hospitals without the formality of certification had, he said, the bulk of professional opinion in its favour. He expressed the hope that its administration would not prove so harsh as to be another form of certification or so exacting as to be another dose of red tape. Lord Onslow, in replying, forecasted the passing of this Bill before the end of the year. The provisions it contained for after-care should often avoid the necessity for further institutional treatment, and facilities were also given for research in mental disease. Lord Riddell and Sir Sydney Russell-Wells also briefly replied. Dr. Goodall, proposing in humorous vein the "Sister Medical Societies," dwelt on the elevating influence of an association of medical men and women. There was, he said, something wrong with the medical fraternity of any community which had no medical society. Sir Humphry Rolleston, Mr. H. J. Waring, Sir William Hale-White, and Dr. Henry Cotton, of New Jersey, replied. Dr. C. Hubert Bond proposed "The Visitors," and Sir Eric Geddes "The Association." Sir Eric Geddes spoke with great sympathy of the vast field for research and investigation opening before mental medicine. Quite apart from hopeful lines of physical treatment, the aid of psychiatry seemed to him, as a layman, almost unexplored. If the case were put before the public clearly and definitely he believed the support obtained for the aims and objects of the Association would be overwhelming. In spite of the tropical heat the dinner was well attended and most successful.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

THE ninth annual conference of this Association was held in the University, Edmund-street, Birmingham, on July 12th, 13th, and 14th.

THURSDAY, JULY 12TH.

The conference was opened by the Right Hon. the Lord Mayor of Birmingham (Sir David Davis), who welcomed all members of the Association to the conference. Sir ARTHUR STANLEY presided over the meeting.

The LORD MAYOR in his opening speech referred to the work done in Birmingham in connexion with tuberculosis, and mentioned the fact that in this town, as in a large number of other towns, the campaign against tuberculosis had resulted in a very definite diminution in the number of new cases of the disease. For some three years before the war there was an average of 4000 new cases of pulmonary tuberculosis reported per annum; last year there were about 1700. The fall in the mortality had not been proportionately so great because it related to cases which commenced years ago, but at the same time there had been a decided drop, the rate for those three years being 0·9 per 1000 of the population. That was a reduction of 60 per cent. in mortality compared with the figure of 50 years ago. Fighting consumption was costing Birmingham nearly £90,000 per annum, but if the reduction in the prevalence of the disease be continued then the city was willing to spend the money.

The subject for the morning session was

Care of Advanced Cases of Tuberculosis, especially as regards Prevention of Infection.

A paper on this subject was read by Prof. J. Robertson (medical officer of health for Birmingham), prepared by the medical officer of health for Edinburgh (Dr. William Robertson), who was unable to be present. The opening paragraph of this paper was the cause of much discussion—namely: "It has yet to be realised by sanitary authorities that the segregation of the advanced case of pulmonary tuberculosis is quite as important as is the isolation of small-pox. From some points of view it is more so, because the spread of small-pox can be arrested in an effectual way by definite measures, while the spread of tuberculosis can only be controlled, as far as we know at present, by preventing the diffusion of the infecting micro-organisms." He further stated that there were far too many sufferers from pulmonary tuberculosis, not a few in an advanced stage of illness, wandering about our streets, resorting to places of public amusement, travelling in trains and trams, and freely scattering infection about them. He condemned home treatment when patients were living in overcrowded and insanitary homes totally unsuitable for the isolation of such a dangerous disease. The housing question, he says, is the Alpha of the tuberculosis problem, but when we discuss the advanced case of tuberculosis we reach the Omega of the subject. "A disease that can levy an annual toll of nearly 40,000 persons every year in our country provides an enemy that must be defeated by methods that are at our hands if we waste less time in discussion and get to business. We know that tuberculosis is preventable, and we have seen how better houses will prevent it." Dr. Robertson considered that warrants for the forcible removal to sanatorium of those who cannot with safety be looked after in their own homes. is a measure that will have to be enforced in the near future. "Surely," he added, "we can afford to be drastic when grappling with such a death-dealing malady." Enforced removal of advanced cases also caused much discussion.

In the succeeding discussion Dr. F. N. Kay Menzies (principal assistant medical officer of health, London County Council) stated that he considered the infectivity of tuberculosis had been greatly exaggerated, and this tended to have a detrimental effect on the work of professional men and to discourage voluntary effort. It also made it difficult for the great organisations in dealing with cases, because it carried with it a stigma on the patient which was hard on him in following his occupation in life. He did not agree that the segregation of tuberculosis was as important as that of small-pox. He further stated that 25 local authorities in this country, Birmingham being one of them, had been given the power compulsorily to remove highly infective cases of tuberculosis for so many months. He had asked these 25 authorities how many compulsory removals they had enforced, and the answer in nearly all instances was not more than one or two. The public would never put up with compulsory removal. He did not agree that housing was the Alpha of the tuberculosis problem. If one factor was to be concentrated upon, the most important was food.

Colonel S. Lyle Cummins (David Davies Professor of Tuberculosis, South Wales and Monmouth) said it would be ridiculous to compare the infectivity of tuberculosis with small-pox, and yet the infectivity of tuberculosis was a terribly real and dangerous thing, and it would not do to discard the importance of infection. He considered that the hope for the future lay in the discovery of a specific remedy, a prophylactic vaccine or both. A few months ago such a hope seemed remote. One variety of tuberculin after another had been tried, and the measure of success had not been very great. The last few weeks have opened up for us new vistas of investigation and effort; and once more, as so often in the past, the new light has come from laboratory research. It would be unwise, as yet, to claim that Prof. Dreyer's "antigen" is the long-sought remedy for which we have waited, but it can be stated with certainty that Dreyer has broken fresh ground and that the results already obtained were decidedly in advance of those of any previous worker, and that they are full of hope for the future.

Dr. W. H. Davison (assistant medical officer of health, Birmingham) considered compulsory removal a broken reed, and thought segregation in the home should be encouraged. It was the most humane method. There was a good scheme working in Birmingham at present whereby a patient can purchase a bed by the hire-system or have a bed lent to him free of charge. There were about 700 beds in use under this scheme, which was doing wonderful work in preventing the spread of infection. He considered it better to spend money on the proper methods of preventing the spread of the disease at home than on the cost of maintenance of an advanced case in an institution.

Dr. A. Fergus Hewat (assistant physician, Royal Infirmary, Edinburgh) considered early cases of tuberculosis might be as infective as the so-called advanced case with an old cavity. Patients who were bedridden and were living in small houses in contact with children he advocated should be removed, as also the cases who were disobedient in their preventive training.

Dr. Marcus Paterson (medical superintendent, Colindale Hospital, Hendon) did not agree with compulsory removal except in the case of the "rotter"—i.e., the man who was disobedient and who made no attempt to control infection. He mentioned the difficulty of removing the prejudice of the public against the sputum flask. He has proved this prejudice by travelling to Birmingham with a third-class ticket and a sputum flask instead of indulging in a first-class ticket in order to secure a comfortable journey. He stated that it had been necessary for him to spit into the flask 16 times, but it had enabled him to have a carriage to himself all the way. He thought the conference would do invaluable work if it helped to overcome this prejudice.

Dr. Ernest Watt (medical officer, Scottish Board of Health) gave some interesting statistical data showing the necessity for the removal of advanced infective cases.

Prof. Cawadias (of the University of Athens) told how the disease had been spread in villages in Greece by the return of emigrants. He considered segregation was the course to which reason prompted, but sentiment would not allow them to be too severe.

Prof. J. Robertson (medical officer of health for Birmingham) said that Dr. W. Robertson's statement that tuberculosis was spread as easily as small-pox he felt was not quite correct. He thought, however, that it was very nearly correct, as there was not much difference when they looked at the fact that very nearly the whole of the community was infected with tuberculosis at one time or another.

Dr. Bolton Thomson (Hastings), Dr. S. Barwise (M.O.H. for Derbyshire), Dr. G. C. Trotter (M.O.H. Islington), Dr. F. L. Moore (tuberculosis officer for Northumberland), and Dr. Alex. Collins (tuberculosis officer for West Ham) also took part in the discussion, the majority of them disagreeing with compulsory removal.

The subject for the afternoon session was:—

Extent and Nature of Damage Done by Tuberculosis derived from Infected Milk: Methods of Prevention.

The discussion was opened by Mr. John D. Watson (Birmingham). He explained the work done by the Birmingham Drainage Board to eliminate tuberculosis from the cattle on their farms. The first tuberculin test applied to cows in 1908 showed that 60 per cent. of the milk cows and 12 per cent. of the heifers were tuberculous. Recurring tests gave encouragement to proceed, and they appeared to prove that by the maintenance of consistent procedure it was possible (within four years of its initiation and at trifling expense) to eliminate tuberculosis from a herd of short-horned cows, which on the first test showed 60 per cent. suffering from the disease. To free a herd from tuberculosis, he said, was not enough; you must be in a position to maintain the herd in a healthy state. He concluded by saying that, important as the attitude of the farmer towards this question may be, the lamentable indifference of the public is the ruling factor. If only milk were a clear fluid like water, and if the public could only see what is so frequently offered to them as clean milk—quite apart from the pathogenic character of the fluid which is offered—they would realise the importance of what the hygienist is trying to do for them.

Sir GILBERT BARLING (Vice-Chancellor of Birmingham University) said that tuberculosis derived from alimentation was especially prone to attack children, especially in glands of the neck and abdomen and bone and joint diseases. He was happy to say, however, that these diseases were distinctly fewer than when he commenced practice 40 years ago. He recommended the appointment of a commission on the question of the pasteurisation of milk, and suggested that something could be done in this direction by the conference.

Mr. JOHN FRASER (surgeon, Royal Hospital for Sick Children, Edinburgh) stated that he had analysed figures for the past ten years and regretted to say that he saw no signs of diminution of surgical tuberculosis amongst children. He considered that the increasing incidence of the present day was most likely due to the widespread unemployment and poverty among our hospital classes. He stated that he was a believer in the overwhelming importance of the bovine infection, and claimed that future investigation would show that it is of even greater importance than we now suspect. The elimination of the bovine infection resolves itself into the preservation of milk from infection, and to secure this the proper means is to arrange for the production and the preparation of the milk that the possibilities of contamination be reduced to a minimum. The first essential of a pure milk production, he stated, is a herd of healthy cows, and this could be guaranteed by the institution of periodical tuberculin tests and the immediate elimination of any animals which react.

Sir HENRY GAUVAIN (medical superintendent, Lord Mayor Treloar Cripples' Hospital, Alton and Hayling Island) exhibited some extremely interesting and instructive lantern slides showing what air therapy and heliotherapy had done towards cures of surgical tuberculosis. He believed that 50 per cent. of the cases of spinal caries, lupus, and infected glands were due to bovine tuberculosis, and no form of food-supply had caused more deaths than the milk-supply of this country.

Mr. BRENNAN DE VINE (chief veterinary officer for Birmingham) stated that during the past 15 years 56 herds of cows had been tested, under the Birmingham scheme, and 37·8 per cent. of the animals had been affected with tuberculosis. He stated that in attempting to eradicate a widespread disease such as bovine tuberculosis in this country, assistance should be offered by the State in order to relieve the burden which falls upon the owner of live stock to the benefit of the general community.

Dr. HAROLD SCURFIELD thought that bovine infection of the human being could be stopped if milk were sufficiently heated. The diminution of the mortality rate of non-pulmonary tuberculosis was largely due to the fact that mothers have been giving their children milk which had been rendered safe by heating.

Mr. WILFRED BUCKLEY (of the National Clean Milk Society) Dr. W. T. MUNRO (medical superintendent, Glenlomond Sanatorium), and Dr. J. WHEATLEY (Shropshire) also took part in the discussion, the latter stating that he did not agree with Dr. Fraser's statement that surgical tuberculosis was on the increase, statistics showed otherwise.

Prof. J. ROBERTSON advocated the pasteurisation of milk and stated there had been an enormous reduction in the mortality from non-pulmonary tuberculosis due to better supervision of the infective consumptive and to the strenuous efforts to free herds from tuberculosis. He stated that Birmingham figures show that non-pulmonary tuberculosis was now a little more than one-third as prevalent as it was 20 years ago.

The annual meeting of the Association and conference of branches was held at the University at 5 P.M., and was presided over by Sir ARTHUR STANLEY. After the usual business of the meeting was over a discussion took place on

Work of Tuberculosis Care Committees; and How the Branches of the Association and Other Kindred Societies can Assist.

Dr. FRANCIS J. H. COUTTS (senior medical officer, Ministry of Health) opened the discussion, and was followed by Miss MCGAW (member of the Council N.A.P.T.) and Mr. G. W. ALLEN (Director, Tuberculous Ex-service Men's Society). They emphasised the necessity of after-care societies to help patients after discharge from sanatoriums. Temporary financial help was not what Care Committees should give. It was the function of a Care Committee to look upon the family of a consumptive as a unit, the whole income of the family should be considered, and the best means found to assist that family in order to enable the patient to live and work under the most satisfactory conditions possible. The necessity for choosing the right type of women for visitors was emphasised; they should be women with plenty of tact to whom patients could feel they could go as a friend and not as an official.

A reception given by the Lord Mayor and Lady Mayoress was held at the City Art Gallery in the evening.

(To be concluded.)

Reviews and Notices of Books.

THE BLOOD-SUPPLY TO THE HEART.

In its Anatomical and Clinical Aspects. By LOUIS GROSS, M.D., C.M., Douglas Fellow in Pathology, McGill University, and Research Associate, Royal Victoria Hospital, Montreal. London: Henry Frowde and Hodder and Stoughton. Pp. 171. 25s.

DR. Louis Gross's monograph on the "Blood-Supply to the Heart" gives an account of the results of his researches on this subject and the special technique which he has employed. Each chapter also contains a short summary of the work of previous investigators and a sketch of the present state of our knowledge in that particular branch of the subject with which it deals. The material was investigated by means of X ray examination after injection with suitable material, and the hearts were finally cleared in oil and sectioned. In the opening chapter the actual technique employed is described in sufficient detail to enable other workers to carry out the method for themselves.

The most striking feature of the book is an interesting series of photographs, which have been very beautifully reproduced, showing the alteration in the relative richness of the blood-supply to the two sides of the heart at different age-periods. At birth the vascularity of the right and left ventricles is approximately equal, but as age advances a marked left-sided preponderance develops, corresponding to the muscular preponderance which has been studied by Müller and other observers. The relative anæmia of the right ventricle is considered to be a potent factor in the ætiology of those diseases which are most liable to prove fatal in old age. In discussing the blood-supply to the valves of the heart, the author puts forward the suggestive hypothesis that the site of election of valvular endocarditis is largely dependent on the vascularity of the different valves at different age-periods. In fœtal life it is the right heart which is most frequently involved. In adults, on the other hand, although relatively few normal valves show a culature, it is the aortic cusp of the mitral valve ch most commonly does so, and it is this cusp which ıost frequently found to be the seat of endocarditis. ıer chapters deal with the normal distribution of coronary arteries, the variations which are liable occur, and the veins of the heart. The important stion of anastomosis between the coronary arteries liscussed; and in this connexion Dr. Gross lays siderable stress on the importance of the increased mess of anastomoses, and the supplementary bloodply from the *arteriæ telæ adiposæ*, which are present the later years of life.

This book demonstrates the value of radiography in s particular branch of anatomical research, and the ıring which anatomy may have upon the clinical blems of cardiology.

---

e Sympathetic Nervous System in Disease.

Second edition. By W. Langdon Brown, M.A., M.D., F.R.C.P., Physician with Charge of Outpatients, St. Bartholomew's Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 161. 10*s.* 6*d.*

The first edition of this book received favourable tice in The Lancet some three years ago. It s been thoroughly revised and new material incorrated. In its present form it contains a general count of visceral disease in relation to dysfunction the sympathetic nervous system, and is suggestive many instances rather than conclusive. What is king largely is pathological confirmation of the esumed faults in the sympathetic mechanisms ncerned in disease-production. We are still greatly ignorance whether a strict line can be drawn tween organic and functional sympathetic disorder; ıen changes in sympathetic ganglia are found stologically we may still query their relationship the clinical phenomena. The truth is that in the ıdy of this part of the nervous system a rational ıpiricism has not as yet been succeeded by a body of ctrine based on pathology. Dr. Langdon Brown clearly aware of the tentative nature of some of his nclusions and admits that some of the views rather favour to-day are no more than plausible speculaons. A beginning has been made, none the less; e sympathetic system is no longer a terra incognita, ıd the clinician is justified in seeking an explanation various clinical types in impairment of sympathetic nction, however far it be from the stage of objective oof. The book has a good index and useful references the literature at the end of each chapter.

---

hronologia Medica.

A Hand-list of Persons, Periods, and Events in the History of Medicine. By Sir D'Arcy Power, K.B.E., F.R.C.S., and C. J. S. Thompson, M.B.E. London: John Bale, Sons and Danielsson, Ltd. 1923. Pp. 278. 10*s.* 6*d.*

This is an excellent and useful little book, ıough as the authors say in their preface the biographies are not intended to be complete, nor does ıe list purport in any sense to be a history of edicine. But it contains a vast amount of information and, we must add, some curious omissions. here is no mention of John of Burgundy, otherwise ohannes de Barba, or John Burgoyne, who may ave been the author of Mandeville's travels and ho is well known as the author of a treatise upon he Black Death of 1348, many MSS. of which are British libraries. Still more strange is the omission f any mention of Victor Horsley. But there are also ntries of the names of comparatively unknown ioneers in sundry branches of science, such, for ıstance, as that of Henry Hickman (1800–1829), a eneral practitioner of Ludlow, who carried out xperiments on animals under anæsthesia by nitrous xide in 1828. Chronologia Medica may be proud f noting him, for his name has escaped the nets both of the Dictionary of National Biography and of Garrison's History. Another interesting entry is that of Adamantios Koraes, otherwise known as Coray, who was a Greek and M.D. of Montpellier (1748–1833). He was a translator of medical books, who left a vast accumulation of notes for an edition of Hippocrates, and he edited the treatise "Airs, Waters, Places," an edition held to be the best extant. On p. 101 we find the following, which, though not exactly inaccurate, is a very loose statement. "1547 St. Mary of Bethlehem Hospital for the Insane founded in London, though Bedlem had been used as an asylum since 1377." An uninstructed reader coming to this passage would imagine the Hospital of St. Mary of Bethlehem and Bedlem to be two different institutions; he would also not gather that the Hospital of St. Mary had really been founded in 1247 as a priory and was first called "hospital" in 1329. The "foundation" in 1547 was of the same nature as the "foundation" of St. Bartholomew's Hospital in 1546, a grudging return of property grabbed by Henry VIII. at the beginning of the Reformation. On p. 45 we note that the elder Bachtishua has his Christian name transliterated as Dschordschis. Why the authors went out of their way to print this queer combination of letters when the simple word "George" would have answered all purposes we do not know. We imagine that it is a French transliteration of the name "Georgees" (to spell it phonetically). Despite these blemishes the book will be found a valuable compilation.

Atoms.

By T. C. Wignall and G. D. Knox. London: Mills and Boom, Ltd. 1923. Pp. 288. 7*s.* 6*d.*

This is a brave attempt, and a very considerably successful one, to explain in popular terms the structure of the atom so that the mystery in which its potential energy is enveloped may be to some extent straightened out for the unscientific. The opening chapter plunges us straight into the story when two of the characters sitting in a railway carriage discuss the possibilities of a *sou* found in the train. Says one of them, "About the most worthless thing one could discover," to which the other replies, "It contains energy equal to 80 million horse-power." The gentleman who thus spoke was "a Johnny on the point of harnessing the atom" according to a popular description of some of his fantastic theories, and he proceeds to explain in simple language, as far as such language will cover the ground, what is meant by atoms, molecules, and electrons, incidentally alluding to the fact that a Greek financier, who is striving to corner the output of the electric workshops of Europe, is anxious to have him for a partner on the ground of his written views. Thereafter follows a thoroughly exciting and well-planned sensational novel, in which the idea is to show what would happen if the atom could be successfully broken up and unlimited energy thereby obtained. As far as has been possible, in dealing with such a theme, the intention has been to be simple, and many associated theories and modern developments have been strictly left on one side. And why not? For, after all, the study of the structure of the atom is extremely recent work, and it is quite likely that some of the results of that work will be found far more valuable than others, while new ideas may be found passing from the realm of fancy to the realm of accepted fact at any moment. It is an excellent notion to familiarise the reading public with the great conceptions of science. It is always quite impossible to follow these great conceptions in laboratory terms, even if the author has the technical qualifications for such writing, unless the reader is an advanced thinker and practical worker himself. To such "Atoms" may or may not appeal. But for a less-equipped audience it may be said that the reading of this novel will place intelligent persons in a position to understand the direction of much modern work and some of its tremendously important meaning. They will be helped to reach this position by a well-planned story of adventure, and we have no hesitation in recommending its perusal.

Endocrine Glands.

Einführung in die Klinik der Inneren Sekretion. By Prof. Dr. G. Peritz, Nervenarzt in Berlin. Berlin: S. Karger. 1923. With 31 illustrations. Pp. 257.

Among various contributions to our knowledge of the endocrine glands and their disorders Dr. Peritz's monograph should take a worthy place. Didactic rather than critical, it contains a fair schematisation of present-day knowledge, which is dealt with under the headings of pituitary, pineal, gonads, adrenals, pancreas, thyroid, parathyroids, and thymus respectively; pluriglandular syndromes receive consideration, on a somewhat meagre scale, while attention is also given to the difficult question of the interrelation of the ductless glands and the nervous system. There are very many references to the appropriate literature of the topics handled, but none to the sources of information, which is matter for regret and detracts from the usefulness of the book. Tables of symptoms and classification of syndromes help the reader to systematise his knowledge.

Epidemic Encephalitis.

L'encéphalite épidémique. By Dr. Louis Reys. Paris: A. Maloine et Fils. 1922. Pp. 144.

This brochure is a clinical study of 150 cases of epidemic encephalitis which occurred in Strasbourg and in Lower Alsace during the period 1919–21. The writer, as Chef de Laboratoire in the Neurological Clinic of the Faculty of Medicine at Strasbourg, had opportunity for carefully recording the clinical phenomena exhibited by the cases and for tracing the tragic after-effects of the malady; from this aspect his study is a fairly complete and useful one. Like some other French authors, Dr. Reys errs, in our opinion, in an over-elaboration of clinical types. Such complexity of classification tends to bewilder the student, whilst those who have investigated similar epidemics deprecate the exaltation of one particular sign or symptom—which, in varying degree, may be seen in all forms of the disease—into the artificial picture of a type. Vertigo frequently occurs in epidemic encephalitis; it is true that when associated with ataxy it may indicate the involvement of the cerebellum, as the histological work of Marinesco proved in 1918, but we hesitate to believe with Dr. Reys that vertigo with ocular disturbances constitutes an essential labyrinthine form of encephalitis, or that further subdivision may be made into pure and associated varieties. In the clinical after-effects noted in this Alsatian outbreak most of the forms so admirably investigated by Mlle. G. Lévy at the Salpêtrière were observed. Of the cases with post-encephalitic sequelæ, paralysis agitans amounted to 40 per cent. approximately; the majority of cases occurred immediately or within one year after the acute attack.

Ocular Neurology.

Manuel de neurologie oculaire. Second edition. By F. de Lapersonne and A. Cantonnet. Paris: Masson et Cie. 1923. Pp. 416. 20*s.*

In this, the second edition of an extremely useful work, the authors have succeeded in producing a valuable and up-to-date treatise on ocular neurology, which cannot fail to appeal both to the student and to the practitioner. The book is divided as before into two parts. The first deals in an admirably clear and detailed manner with the anatomy and physiology of the nervous mechanism of the eye, with the symptomatology of its various pathological states and with methods of clinical examination. The second part, which has been enlarged and brought up to date, contains an account of the ocular manifestations of various nervous and general diseases. This section would bear still further amplification.

The book strikes us as being primarily suited to the student. The anatomical descriptions are particularly lucid and good, though we venture to disagree with the rather low value (21°) given for the angle between the orbital axis and the mid-line. We should also like to have seen a fuller description of the mechanism of production of the various clinical signs. Of course this must be very largely controversial, but it would add much to the interest of the work if the realms of hypothesis were occasionally entered. For example, the student would be more likely to remember the existence of the Tournay reaction if he were given some idea, even if necessarily purely speculative, of its mechanism. The illustrations are good, with the exception of the two presentations of the fundus oculi, which might with advantage have been replaced by plates from any standard text-book of ophthalmology.

Diseases of the Heart.

Herzkrankheiten. By Privatdozent Dr. P. Schrumpf, Assistent am Med-poliklinischen Institut der Universität Berlin. Leipzig: Georg Thieme. 1922. Pp. 200. 4*s.* 7*d.*

This book, it is stated, is intended for the student and the general practitioner, and for further information on the subject the reader is referred to the author's larger work "Klinische Herz-diagnostik," 1919. The first two chapters set out anatomy and clinical methods for investigating the heart. The next 15 chapters deal with diseases of the heart, and the final chapter discusses treatment of the various forms of heart disease. The description of methods is meagre, and not sufficiently explicit to be of use to those who would be likely to read such an elementary book. The chapters on diseases of the heart are clear and readable, but require to be supplemented by the use of a larger book. The value of the tracings reproduced, which are drawings of the originals, is diminished by the unfortunate absence of time markings.

On the whole, considering the brevity of the volume, the author has selected wisely.

Autobiographical Studies in Modern Medicine.

Die Medizin der Gegenwart in Selbstdarstellungen. Vols. I. and II. Edited by Prof. L. R. Grote, Privatdozent at the University of Halle. Leipzig: Felix Meiner. 1923. Vol. I. Pp. 239. 8*s.* Vol. II. Pp. 250. 8*s.*

Prof. Grote's personal contribution to the first volume is limited to an 11-page introduction in which he points out that the history of medicine, like history in general, is the record of its great men. To attempt to sketch the development of medical science as an impersonal thing would be not only to rob it of colour, but also of form. So he has induced six of his most prominent colleagues to give short autobiographical records of the parts they played in developing their respective specialties. After his prologue, the editor retires, and the rest of the book contains the life-histories, with portraits, of Alfred Erich Hoche, Hermann Kümmell, Felix Marchand, Friedrich Martius, Wilhelm Roux, and Robert Wiedersheim. The second volume includes autobiographies of Dietrich Barfurth, Paul Grawitz, Ferdinand Hueppe, Hans Horst Meyer, Franz Penzoldt, F. Julius Rosenbach, Friedrich Schultze, and Hugo Schulz. It is probable that the information thus provided during the life of, and by, the person concerned is more reliable than the average obituary notice which is so often stultified by blind observance of the rule "De mortuis . . . ." But though a biopsy may yield fuller and more accurate information than a necropsy, there are certain difficulties attached to the former method, however anæsthetic the auto-vivisector may be. The six leaders of the medical profession who have turned their insides out for the benefit of their colleagues are to be congratulated on the conscientiousness and skill with which they have performed their allotted task. To be at once truthful and modest in such a matter must be very difficult indeed.

THE LANCET.

LONDON: SATURDAY, JULY 21, 1923.

RESEARCH IN MENTAL DISEASE.

THE Medico-Psychological Association of Great Britain and Ireland completed last week in London its eighty-second annual meeting. The atmosphere of the meeting was one of expectancy; at the annual banquet Lord ONSLOW expressed his belief that the Mental Treatment Bill would become law before the end of the year, when the Statute-book would no longer recognise the term "lunatic asylum." Sir ERIC GEDDES, speaking impressively on the same theme, was sure that the use of the term "mental hospital" would greatly benefit the attainment of the objects of the Association. He alluded to the vast field for research, for investigation, for treatment, and for cure, now open to the mental hospitals if adequately supported; if the case were put before the public clearly and definitely the response, he said, would be overwhelming. Every alienist knows that research must come first and provision has actually been made for research in the Bill. Dr. EDWIN GOODALL'S presidential address to the Association was largely taken up with an inquiry into the rôle played by toxic bodily conditions in disorders of the mind; and Dr. HENRY COTTON, lecturer in psychopathology at Princeton University, made a very convincing statement of his own experience in regard to chronic sepsis. Five years given up to the study of endocrine disturbance and gland therapy in functional mental order had led him to no decisive result, but eradication of chronic sepsis had been rewarded by an immediate increase in the recovery rate of his patients from 37 to 85 per cent., so that he had come to regard disease of the brain tissue as the fundamental condition, and psychogenic factors as precipitative rather than causative of psychosis. Other notable contributions at this meeting were Dr. C. LOVELL'S discovery in anxiety cases of increased nucleation of the interlobular connective tissue of the pancreas, an observation by Sir FREDERICK MOTT and Dr. IDA ROBERTSON of complete atrophy of the cellular elements of the pituitary body in dementia præcox, and Dr. J. WALKER'S demonstration of vagotonia in the same condition.

Already a number of mental hospitals have appointed an additional medical officer, whose time will be devoted chiefly or wholly to pathological investigations. There are a few examples, among which Cardiff City Mental Hospital is perhaps the most noteworthy, of institutions possessing extensive laboratories and a comparatively large staff of investigators. In a large hospital, especially in one connected with a university, such a development of this side of the work is eminently desirable and feasible. It is impossible, however, for work of this nature and extent to be undertaken in every mental hospital in the country; routine work of a simple nature can be undertaken with advantage, but more difficult work must often be sent elsewhere, and deliberate research will demand facilities which are available only in specially equipped laboratories. These considerations have led to the establishment of central laboratories designed to serve a group of mental hospitals. An example of such work is afforded in the thirteenth annual report of the Scottish Western Asylums' Research Institute. Much of the work done during the year has been of a routine nature, and medical officers from the asylums interested have attended the institute in order to acquire a knowledge of laboratory technique. At the same time several lines of research have been followed—mainly of a chemical nature, including an investigation of the blood-sugar content in emotional states, and determination of the basal metabolic rate in dementia præcox. In some cases where the underlying cause appeared to be infective, autogenous vaccines have been prepared, and an attempt was made to influence conditions apparently due to intestinal auto-intoxication by administering milk soured by the *Bacillus acidophilus*. This interesting experiment yielded improvement in general health, although no effect was observed on the mental condition of the patients.

A similar venture on a somewhat larger scale is represented by the Birmingham Pathological Laboratories at Hollymoor Mental Hospital, which have been established by the Joint Board of Research for Mental Disease, and were opened at a meeting held on June 16th, attended by the Minister of Health. These laboratories, which are under the direction of Sir FREDERICK MOTT, are equipped for all varieties of work, and for purposes of routine investigation are intended to serve the mental hospitals of the Midlands. Mental hospitals are invited to coöperate, either by making an annual contribution or by sending material for examination at charges to be fixed by arrangement. At present there are, unfortunately, legal restrictions which prevent the authorities of mental hospitals from contributing adequately to such a scheme as this, and the Birmingham laboratories are dependent in part on funds which have been raised privately. The present arrangements are regarded as only a beginning, and it is probable that the department will be transferred later to the Birmingham University Laboratories, where the work will be in direct association with the general pathological work of the University.

◆

THE INTERNATIONAL CONGRESS OF SURGERY.

THE International Society of Surgery has just concluded in London its Sixth Triennial Congress. We are able to print this week a report of the inaugural session at which the delegates were officially welcomed and Sir WILLIAM MACEWEN delivered a presidential address, and of the first scientific session which was devoted to reports and discussion on the surgery of endocrine glands. We have had among us a body of men whose names are household words in their profession. Twenty-four countries, ranging from Roumania and Poland to Chili and Peru, have sent their greatest surgeons to tell us of their discoveries, to inspire us with their own enthusiasm, and to stimulate us to emulation. In the amazing progress which surgery has made in the last 30 years Britain has taken her full share, and the sons of HUNTER and of LISTER are not unworthy of their great ancestry. But just because British surgeons have striven to keep in the van, they are the better able to appreciate the great men of other countries who have fought so hard to wring from Nature the secrets of their art, and they are the more eager to applaud the victories they have won. Towering above them all in age and experience, the very Nestor of surgery, is William Keen. Eighty-six years of life and 64 of surgery have still left him young, and it is difficult to realise that he was a pioneer in America when Lister was still feeling his way towards antisepsis, and when abdominal surgery was a distant dream. William Mayo, of Rochester, the head, with his brother, of the greatest surgical organisation in the world, brings with him Donald Balfour, one of his ablest captains. From its vast resources the Mayo Clinic provides a formidable proportion of the surgical literature of the world, and we owe no small part of modern abdominal surgery to its leaders. Representing American orthopædics we have Edville G. Abbott, who has done so much to improve the treatment of spinal curvature. Charles H. Frazier represents neurology, and to him we owe many ingenious methods for dealing with the difficult problems presented by the gasserian ganglion and pituitary tumours. George Crile has come to teach us how to operate by stealth, so that even the subconscious nervous system of the patient may not be injured by the operation which he cannot feel. From Canada we welcome Frederick G. Banting, whose discovery of insulin has revolutionised the treatment of diabetes and given a powerful stimulus to the study of the endocrine glands. France has always been famous for her surgeons, and her list includes many familiar names. Theodore Tuffier calls to mind brilliant advances in thoracic surgery, A. Gosset and René Leriche in the surgery of the peripheral nervous system. Henri Hartmann in gynæcology and Louis Bazy in the urinary tract are masters, whilst to De Martel we owe a whole range of ingenious instruments which he applies with exquisite skill in the surgery of the brain. Belgium sends us Charles Willems, whose daring methods of treating war infections of the knee by mobilisation revolutionised our outlook on the surgery of septic joints, and Albin Lambotte, one of the pioneers in the surgery of the bones and in the operative treatment of fractures. Prof. V. Putti, from the famous school of Bologna, has shown us how to obtain from amputation stumps movements never before thought possible. From Berne, made famous by Theodor Kocher, comes Fritz de Quervain, to whom we owe a brilliant book on surgical diagnosis, and who is one of the greatest living authorities on endemic goitre. A few names chosen at random from a long list can give little idea of the brilliant intellects who have met at the Congress. Still less can a few short sentences give any adequate conception of the treasures which years of labour have enabled these men and their colleagues to hand down as a priceless possession to posterity. The surgeons of Britain are indeed proud to welcome a body of men, every one of whom has added lustre to a great profession, and the people of Britain will rejoice that through the lips of our own Prince Ambassador they were able to pay homage to those whose devoted labours have won such blessings for humanity.

THE SPAHLINGER TREATMENT.

The paper on the Spahlinger vaccine by Dr. E. H. Colbeck and Dr. S. Roodhouse Gloyne, and the letters on the same subject published in this issue of The Lancet add a good deal, but not as much as we want, to our knowledge of this subject. We are told of the results, immediate and late, of this treatment in a considerable number of cases, and we are left by Dr. Colbeck and Dr. Gloyne to draw our own conclusions. In withholding the panegyric with which new remedies are usually ushered into the world, they have acted with wisdom as well as with restraint, and have proved themselves conversant with the history of therapeutics. The usual record of a new remedy may be illustrated as a tracing—a sharp rise, a culmination of brief duration, and a slow decline ending either at a low level or, sad to say, in the base line of oblivion. This last is the fate of many remedies, as we all know. Yet the incorrigible optimism of man is doubtless an asset to the race, and the indiscriminate scepticism of the senior medical student towards the youthful therapeutic enthusiasms of his teachers is sometimes ill-founded. We may then do well to scrutinise the evidence supporting the Spahlinger case before we discard it as unproven. A perusal of the cases hitherto published brings out one very important point. They were, as a rule, advanced cases, and in many the disease was active as well as advanced. To undertake the cure of an early case of tuberculosis is often like rushing to the aid of the victor; it is not infrequently a work of supererogation. During the recent tuberculin revival, "cures" were effected in persons whose only sign of tuberculosis was a positive tuberculin reaction. If, and we would emphasise this *if*, the Spahlinger treatment is uniformly and permanently beneficial in febrile cases with signs of advanced pulmonary disease, then the viability of this treatment is assured. But, considering how erratic the course of even advanced and febrile pulmonary tuberculosis may be, we must have many more records than we possess at present of the results of this treatment; the *ex uno disce omnes* principle must be reversed. Another point is concerned with the experimental evidence in the case. Is it supported by controlled guinea-pig and other animal tests? More human beings recover from, than die of, infection with the tubercle bacillus, and man is therefore for this, as well as other reasons, an unsuitable test subject. But the guinea-pig experimentally infected by the tubercle bacillus almost invariably dies in a few months. Has the tuberculous guinea-pig been cured by the Spahlinger preparations?

The problems of tuberculosis being already singularly intricate and confused, it is a pity that, so far as the Spahlinger treatment is concerned, confusion has been worse confounded by the secretiveness which has marked its production and its methods for distribution. Had Mr. Spahlinger published his researches from time to time, they could have been checked by other workers, and much valuable time would possibly have been saved. At present we do not even know whether the composition of the vaccines and serums now trickling out in a fitful stream from the Spahlinger laboratory is that of the vaccines and serums which were, apparently, very effective in 1914. We are given highly laudatory reports from physicians who have visited Mr. Spahlinger in Switzerland, but all these visitors were not expert pathologists, serologists, and bacteriologists. Even if they had been thus qualified, how could they judge of the value of a remedy, the manufacturing processes of which were jealously guarded? These visits of inspection were little short of farcical what time the actual methods of production were kept secret. The physicians who have returned from their tour of inspection with the docile fervour of a religious pilgrim have, of course, acted with perfect honesty, and who shall blame them for that faith which accepts as gospel "the evidence of things unseen"? But those of us to whom this kind of faith is denied will suspend judgment until such time as sufficient of the remedy has been submitted to one or other of the research institutes which have made no secret of their willingness to supervise a valid test.

"Ne quid nimis."

MEDICAL EXAMINATIONS FOR MOTOR DRIVERS.

COMPLICATIONS which may arise from the new legislation as to medical examinations for motor drivers and set out in our Paris letter, June 30th, are well discussed in a recent number of *Le Scalpel* (vol. lxxvi., p. 289). What, for example, is the physician to do who is consulted by an epileptic chauffeur? If the chauffeur insists on continuing his employment, the physician is faced with the disagreeable alternatives of warning the chauffeur's employer or being held responsible for some fatal accident at a later date. The problem is almost as delicate as that which often arises in connexion with venereal disease, and it raises the question of compulsory health certificates for motor drivers. Among the proposals recently made to the Academy of Medicine in Paris it was suggested that no such licence should be given to anyone under the age of 21, that chauffeurs suffering from faulty vision or hearing should be subjected to a medical examination by a specialist every year, and that no licence should be given to anyone without a medical examination at which the heart, the arterial pressure, and the functions of equilibrium and coördination have been found to be in good order. The first of these three requirements seems to be over-shooting the mark; many fools remain reckless all their lives, and many persons are level-headed while still in their teens. But the other two conditions are worthy of serious consideration; after a recent accident it transpired that the owner-driver of a car was totally deaf, being accompanied on that occasion by his wife, who was also deaf, and it would be well if such diseases as epilepsy, chronic alcoholism, and addiction to drugs were made disqualifications for driving licences. The objection may be raised that even if medical examinations were enforced as a step to qualifying for a driving licence, diseases such as addiction to drugs could easily be concealed, and the true facts of the case might not be revealed till an inquest was held on the driver's victim. But even if the mesh of the medical examiner's net were to prove too coarse for certain slim applicants for driving licences, it would yet serve a useful purpose in discouraging some of the least physically fit from applying for a licence. It would, of course, be possible by a medical examination to give only a partial guarantee of physical and mental fitness; a driver may be physically and mentally fit enough to amble at ten miles an hour through a deserted country lane, whereas he may break down in congested traffic. At an inquest recently commented on in a leading article in the *Manchester Guardian*, the driver's excuse for the accident was, "I completely lost my head." As pointed out in the journal, the driver would probably have been able to pass any likely official test in the week before the accident. It is evident, therefore, that no tests, medical or other, can guarantee a foolproof state of affairs, but it would be well if efficiency tests for motor driving were made as searching and stringent as possible.

PUERPERAL MORBIDITY.

Dr. Eula Eno,[1] of Des Moines, Iowa, has made a study of puerperal morbidity based on the records of about 7000 cases equally distributed between intern and extern practice at the Woman's Medical College of Pennsylvania during the period from 1906–1921. The English standard of morbidity was chosen according to which any puerperal case is regarded as morbid in which there is a rise of temperature to 100° F. for three successive days or longer. In the total of 3500 intern patients there were 300 cases of puerperal morbidity, or 8·6 per cent., with 10 deaths; 202 were primiparæ and 98 multiparæ—a percentage incidence of 11·5 and 5·6 respectively—so that puerperal morbidity is twice as common among primiparæ. In the extern practice there were 71 cases of morbidity, or 2·0 per cent., with no deaths; 23, or 3·2 per cent., were primiparæ, and 48, or 1·7 per cent., multiparæ. A study of the morbidity during each of the five-year periods shows a progressive fall in the incidence, the percentage in the intern practice being 11·3 in the first period, 9·7 in the second, and 7·5 in the third, while in the extern practice the incidence fell from 2·16 per cent. in the first period to 1·6 per cent. in the third. There was a definite increase in morbidity in non-operative cases in primiparæ as compared with multiparæ, which was probably due to the influence of protracted labour and repeated vaginal examinations. Gonorrhœa played a considerable part in the causation of morbidity, as there was either bacteriological or definite clinical evidence of that disease as an ætiological factor in puerperal morbidity in 36 per cent. of primiparæ and in 20 per cent. of multiparæ. In a large class, ranging from 33 to 75 per cent. of the total patients, in which the symptoms were very mild, no definite ætiological factor could be found. There was a definite drop in the incidence of post-operative morbidity, but it was less than that of non-operative morbidity. The operative procedures succeeded by morbidity were as follows in decreasing order of frequency: intra-uterine douche, version and extraction with craniotomy, manual removal of placenta following some other procedure, insertion of bag following some other procedure, Cæsarean section, version and extraction, high forceps, mid forceps, breech extraction, low forceps, manual removal of placenta, insertion of bag, the sequence being practically the same in intern and extern practice.

A MEDICAL GATHERING AT THE SOUTH LONDON HOSPITAL.

PLEASURE before business was an excellent hot weather rule at a meeting of the London Association of the Medical Women's Federation which was held at the South London Hospital for Women on July 10th. Refreshed by a strawberry tea in the hospital gardens at 4.30, nearly all the guests willingly undertook a climb to the roof preliminary to inspecting the hospital under the guidance of Miss M. M. Chadburn, its senior surgeon. It will be remembered that the hospital was founded and incorporated in 1912 to make further provision for medical treatment of women by members of their own sex; to provide, in addition to ordinary hospital accommodation, private wards for women of limited means at low inclusive fees; and to afford further scope for postgraduate training for medical women. The hospital overlooks Clapham Common, and is equipped not only with what have come to be considered the essentials of a modern hospital, but with those amenities which do much to minimise the differences between hospital and home. For example, the lack of some privacy in hospitals is a source of dismay both to probationers and to new patients, though it may be admitted that both classes of inmates soon get accustomed to living in close community with their fellows. At the South London Hospital, however, there are not only separate bedrooms for nurses but cubicles for wardmaids, while besides big wards single rooms are provided for patients at 6 guineas a week each, double rooms at 4 guineas, and cubicles at 5 guineas. The ancillary departments—X ray, electrical, dispensing, and pathological—are well disposed, the last-named block being especially light and airy. Practically all the wards have large balconies which are specially appreciated in the treatment of children. The admirably appointed kitchens and the boiler room with duplicate plant were open for inspection. As to clinical work, operations were being performed in the theatre by Miss E. Davies-Colley, and before the of surgery, is William Keen. Eighty-six years of life and 64 of surgery have still left him young, and it is difficult to realise that he was a pioneer in America when Lister was still feeling his way towards antisepsis, and when abdominal surgery was a distant dream. William Mayo, of Rochester, the head, with his brother, of the greatest surgical organisation in the world, brings with him Donald Balfour, one of his ablest captains. From its vast resources the Mayo Clinic provides a formidable proportion of the surgical literature of the world, and we owe no small part of modern abdominal surgery to its leaders. MEDICAL EXAMINATIONS FOR MOTOR DRIVERS.

COMPLICATIONS which may arise from the new legislation as to medical examinations for motor drivers and set out in our Paris letter, June 30th, are well discussed in a recent number of *Le Scalpel* (vol. lxxvi., p. 289). What, for example, is the physician to do who is consulted by an epileptic chauffeur? If the chauffeur insists on continuing his employment, the physician is faced with the disagreeable alternatives of warning the chauffeur's employer or being held responsible for some fatal accident at a later date. The problem is almost as delicate as that which often arises in connexion with venereal disease, and it raises the question of compulsory health certificates for motor drivers. Among the proposals recently made to the Academy of Medicine in Paris it was suggested that no such licence should be given to anyone under the age of 21, that chauffeurs suffering from faulty vision or hearing should be subjected to a medical examination by a specialist every year, and that no licence should be given to anyone without a medical examination at which the heart, the arterial pressure, and the functions of equilibrium and coördination have been found to be in good order. The first of these three requirements seems to be over-shooting the mark; many fools remain reckless all their lives, and many persons are level-headed while still in their teens. But the other two conditions are worthy of serious consideration; after a recent accident it transpired that the owner-driver of a car was totally deaf, being accompanied on that occasion by his wife, who was also deaf, and it would be well if such diseases as epilepsy, chronic alcoholism, and addiction to drugs were made disqualifications for driving licences. The objection may be raised that even if medical examinations were enforced as a step to qualifying for a driving licence, diseases such as addiction to drugs could easily be concealed, and the true facts of the case might not be revealed till an inquest was held on the driver's victim. But even if the mesh of the medical examiner's net were to prove too coarse for certain slim applicants for driving licences, it would yet serve a useful purpose in discouraging some of the least physically fit from applying for a licence. It would, of course, be possible by a medical examination to give only a partial guarantee of physical and mental fitness; a driver may be physically and mentally fit enough to amble at ten miles an hour through a deserted country lane, whereas he may break down in congested traffic. At an inquest recently commented on in a leading article in the *Manchester Guardian*, the driver's excuse for the accident was, "I completely lost my head." As pointed out in the journal, the driver would probably have been able to pass any likely official test in the week before the accident. It is evident, therefore, that no tests, medical or other, can guarantee a foolproof state of affairs, but it would be well if efficiency tests for motor driving were made as searching and stringent as possible.

PUERPERAL MORBIDITY.

Dr. Eula Eno.[1] of Des Moines, Iowa, has made a study of puerperal morbidity based on the records of about 7000 cases equally distributed between intern and extern practice at the Woman's Medical College of Pennsylvania during the period from 1906–1921. The English standard of morbidity was chosen according to which any puerperal case is regarded as morbid in which there is a rise of temperature to 100° F. for three successive days or longer. In the total of 3500 intern patients there were 300 cases of puerperal morbidity, or 8·6 per cent., with 10 deaths; 202 were primiparæ and 98 multiparæ—a percentage incidence of 11·5 and 5·6 respectively—so that puerperal morbidity is twice as common among primiparæ. In the extern practice there were 71 cases of morbidity, or 2·0 per cent., with no deaths; 23, or 3·2 per cent., were primiparæ, and 48, or 1·7 per cent., multiparæ. A study of the morbidity during each of the five-year periods shows a progressive fall in the incidence, the percentage in the intern practice being 11·3 in the first period, 9·7 in the second, and 7·5 in the third, while in the extern practice the incidence fell from 2·16 per cent. in the first period to 1·6 per cent. in the third. There was a definite increase in morbidity in non-operative cases in primiparæ as compared with multiparæ, which was probably due to the influence of protracted labour and repeated vaginal examinations. Gonorrhœa played a considerable part in the causation of morbidity, as there was either bacteriological or definite clinical evidence of that disease as an ætiological factor in puerperal morbidity in 36 per cent. of primiparæ and in 20 per cent. of multiparæ. In a large class, ranging from 33 to 75 per cent. of the total patients, in which the symptoms were very mild, no definite ætiological factor could be found. There was a definite drop in the incidence of post-operative morbidity, but it was less than that of non-operative morbidity. The operative procedures succeeded by morbidity were as follows in decreasing order of frequency: intra-uterine douche, version and extraction with craniotomy, manual removal of placenta following some other procedure, insertion of bag following some other procedure, Cæsarean section, version and extraction, high forceps, mid forceps, breech extraction, low forceps, manual removal of placenta, insertion of bag, the sequence being practically the same in intern and extern practice.

A MEDICAL GATHERING AT THE SOUTH LONDON HOSPITAL.

PLEASURE before business was an excellent hot weather rule at a meeting of the London Association of the Medical Women's Federation which was held at the South London Hospital for Women on July 10th. Refreshed by a strawberry tea in the hospital gardens at 4.30, nearly all the guests willingly undertook a climb to the roof preliminary to inspecting the hospital under the guidance of Miss M. M. Chadburn, its senior surgeon. It will be remembered that the hospital was founded and incorporated in 1912 to make further provision for medical treatment of women by members of their own sex; to provide, in addition to ordinary hospital accommodation, private wards for women of limited means at low inclusive fees; and to afford further scope for post-graduate training for medical women. The hospital overlooks Clapham Common, and is equipped not only with what have come to be considered the essentials of a modern hospital, but with those amenities which do much to minimise the differences between hospital and home. For example, the lack of some privacy in hospitals is a source of dismay both to probationers and to new patients, though it may be admitted that both classes of inmates soon get accustomed to living in close community with their fellows. At the South London Hospital, however, there are not only separate bedrooms for nurses but cubicles for wardmaids, while besides big wards single rooms are provided for patients at 6 guineas a week each, double rooms at 4 guineas, and cubicles at 5 guineas. The ancillary departments—X ray, electrical, dispensing, and pathological—are well disposed, the last-named block being especially light and airy. Practically all the wards have large balconies which are specially appreciated in the treatment of children. The admirably appointed kitchens and the boiler room with duplicate plant were open for inspection. As to clinical work, operations were being performed in the theatre by Miss E. Davies-Colley, and before the of surgery, is William Keen. Eighty-six years of life and 64 of surgery have still left him young, and it is difficult to realise that he was a pioneer in America when Lister was still feeling his way towards antisepsis, and when abdominal surgery was a distant dream. William Mayo, of Rochester, the head, with his brother, of the greatest surgical organisation in the world, brings with him Donald Balfour, one of his ablest captains. From its vast resources the Mayo Clinic provides a formidable proportion of the surgical literature of the world, and we owe no small part of modern abdominal surgery to its leaders. Representing American orthopædics we have Edville G. Abbott, who has done so much to improve the treatment of spinal curvature. Charles H. Frazier represents neurology, and to him we owe many ingenious methods for dealing with the difficult problems presented by the gasserian ganglion and pituitary tumours. George Crile has come to teach us how to operate by stealth, so that even the subconscious nervous system of the patient may not be injured by the operation which he cannot feel. From Canada we welcome Frederick G. Banting, whose discovery of insulin has revolutionised the treatment of diabetes and given a powerful stimulus to the study of the endocrine glands. France has always been famous for her surgeons, and her list includes many familiar names. Theodore Tuffier calls to mind brilliant advances in thoracic surgery, A. Gosset and René Leriche in the surgery of the peripheral nervous system. Henri Hartmann in gynæcology and Louis Bazy in the urinary tract are masters, whilst to De Martel we owe a whole range of ingenious instruments which he applies with exquisite skill in the surgery of the brain. Belgium sends us Charles Willems, whose daring methods of treating war infections of the knee by mobilisation revolutionised our outlook on the surgery of septic joints, and Albin Lambotte, one of the pioneers in the surgery of the bones and in the operative treatment of fractures. Prof. V. Putti, from the famous school of Bologna, has shown us how to obtain from amputation stumps movements never before thought possible. From Berne, made famous by Theodor Kocher, comes Fritz de Quervain, to whom we owe a brilliant book on surgical diagnosis, and who is one of the greatest living authorities on endemic goitre. A few names chosen at random from a long list can give little idea of the brilliant intellects who have met at the Congress. Still less can a few short sentences give any adequate conception of the treasures which years of labour have enabled these men and their colleagues to hand down as a priceless possession to posterity. The surgeons of Britain are indeed proud to welcome a body of men, every one of whom has added lustre to a great profession, and the people of Britain will rejoice that through the lips of our own Prince Ambassador they were able to pay homage to those whose devoted labours have won such blessings for humanity.

◆

THE SPAHLINGER TREATMENT.

The paper on the Spahlinger vaccine by Dr. E. H. Colbeck and Dr. S. Roodhouse Gloyne, and the letters on the same subject published in this issue of The Lancet add a good deal, but not as much as we want, to our knowledge of this subject. We are told of the results, immediate and late, of this treatment in a considerable number of cases, and we are left by Dr. Colbeck and Dr. Gloyne to draw our own conclusions. In withholding the panegyric with which new remedies are usually ushered into the world, they have acted with wisdom as well as with restraint, and have proved themselves conversant with the history of therapeutics. The usual record of a new remedy may be illustrated as a tracing—a sharp rise, a culmination of brief duration, and a slow decline ending either at a low level or, sad to say, in the base line of oblivion. This last is the fate of many remedies, as we all know. Yet the incorrigible optimism of man is doubtless an asset to the race, and the indiscriminate scepticism of the senior medical student towards the youthful therapeutic enthusiasms of his teachers is sometimes ill-founded. We may then do well to scrutinise the evidence supporting the Spahlinger case before we discard it as unproven. A perusal of the cases hitherto published brings out one very important point. They were, as a rule, advanced cases, and in many the disease was active as well as advanced. To undertake the cure of an early case of tuberculosis is often like rushing to the aid of the victor; it is not infrequently a work of supererogation. During the recent tuberculin revival, "cures" were effected in persons whose only sign of tuberculosis was a positive tuberculin reaction. If, and we would emphasise this *if*, the Spahlinger treatment is uniformly and permanently beneficial in febrile cases with signs of advanced pulmonary disease, then the viability of this treatment is assured. But, considering how erratic the course of even advanced and febrile pulmonary tuberculosis may be, we must have many more records than we possess at present of the results of this treatment; the *ex uno disce omnes* principle must be reversed. Another point is concerned with the experimental evidence in the case. Is it supported by controlled guinea-pig and other animal tests? More human beings recover from, than die of, infection with the tubercle bacillus, and man is therefore for this, as well as other reasons, an unsuitable test subject. But the guinea-pig experimentally infected by the tubercle bacillus almost invariably dies in a few months. Has the tuberculous guinea-pig been cured by the Spahlinger preparations?

The problems of tuberculosis being already singularly intricate and confused, it is a pity that, so far as the Spahlinger treatment is concerned, confusion has been worse confounded by the secretiveness which has marked its production and its methods for distribution. Had Mr. Spahlinger published his researches from time to time, they could have been checked by other workers, and much valuable time would possibly have been saved. At present we do not even know whether the composition of the vaccines and serums now trickling out in a fitful stream from the Spahlinger laboratory is that of the vaccines and serums which were, apparently, very effective in 1914. We are given highly laudatory reports from physicians who have visited Mr. Spahlinger in Switzerland, but all these visitors were not expert pathologists, serologists, and bacteriologists. Even if they had been thus qualified, how could they judge of the value of a remedy, the manufacturing processes of which were jealously guarded? These visits of inspection were little short of farcical what time the actual methods of production were kept secret. The physicians who have returned from their tour of inspection with the docile fervour of a religious pilgrim have, of course, acted with perfect honesty, and who shall blame them for that faith which accepts as gospel "the evidence of things unseen"? But those of us to whom this kind of faith is denied will suspend judgment until such time as sufficient of the remedy has been submitted to one or other of the research institutes which have made no secret of their willingness to supervise a valid test.

but here in this room we are not the whole Congregation. We are surrounded by the faces of the unforgotten dead who require of us that we accord no honour to success unless that success has been attained with due regard to certain ancient principles which are still the glory of the profession.

I will therefore say—firstly, that every new fact uncovered and every new idea conceived in Rochester has been freely and promptly communicated to the profession, and the whole surgical world have been free students of the Mayo Clinic; secondly, that the inheritance of an ancient obligation has been faithfully accepted and the afflicted poor have a generous share in the benefits of the institution; thirdly, that success and praise have in no way misguided the workers in their quest for perfection. Emerson has said that if a man can do something, even the making of a mouse-trap, better than anyone else, no matter where he hides himself, the world will make a beaten path to his door. Mayo has proved this true, but those who know him know that no one is more likely to slip into the Surgeons' Valhalla murmuring apologies for the quality of *his* mouse-trap; and lastly, that the work of this notable family has contributed substantially to the diminution of that terror of the knife which has hitherto added so much to the distress of afflicted humanity.

Therefore, Prof. Jamieson concluded, it is not only as the promoter of a colossal enterprise and as a distinguished figure in surgical research, but as a true man, modest, charitable, and humane, that in the name of this Congregation I present to you William James Mayo for the Degree of Doctor of Science.

THE BEIT MEMORIAL FELLOWSHIPS.

AT a recent meeting of the trustees of the Beit Memorial Fellowships for Medical Research, Sir James K. Fowler, the honorary secretary, presented a review of the fellowships from their beginning in 1910 to 1923. During that period, said Sir James Fowler, 79 fellowships had been awarded; but for the war this number would have been considerably greater. In 1914 nearly the whole body of Fellows resigned in order to join one or other of the public Services; all of these who so desired were ultimately reinstated, but during the war years very few appointments were made. The value of the fellowships, originally £250 per annum, was in 1919 increased to £300, and in 1920 to £400; in 1922 they were classified as junior fellowships (value £350 per annum), fourth-year fellowships (£400), and senior fellowships (£600). The main object of this classification was to remove, as far as possible, the objection that the fellowships opened up no career to those possessed of the spirit of research and likely to become qualified for the highest positions in teaching and research work. It was now possible for candidates to see seven years ahead—three as a junior fellow, one as a fourth-year fellow, and three as a senior fellow. The income of the trust for the last financial year was about £11,500. In April, 1922, a report on the after-careers of the first 50 Fellows showed that two had gained fellowships of the Royal Society, four had become directors of research institutes, eight were professors, eight university lecturers, three were hospital physicians in charge of special and research departments, one was on a scientific research expedition. One only was engaged in medical practice. Four women Fellows had married, and most of the others were holding responsible appointments or pursuing independent research. Of the 29 Fellows since elected, 16 still hold fellowships. After the report had been received, the trustees proceeded to the election of Fellows. The number of candidates was 36, the largest since the first election. The following are the names of the elected candidates, with an indication of the direction of research or proposed research:—Senior Fellowship: Dr. David Keilin, life-history of parasitic protista and physiology of parasitic metazoa. Fourth-year Fellowship: Miss Katherine H. Coward, D.Sc., investigation into processes of metabolism, nutrition, and growth of young animals, particularly with references to deficiency diseases. Junior Fellowships (ten were awarded instead of six as stated in the advertisements, on account of the high qualifications of candidates): Dr. J. M. H. Campbell (1) oxygen consumption and pulmonary ventilation during and after work in chronic heart and lung disease, and total metabolism and "efficiency" of work in these and other diseased conditions; (2) changes in capillary circulation in the skin in dermographia, urticaria, angioneurotic œdema, and certain chronic nervous diseases. Dr. C. G. Lambie, influence of insulin upon fat and protein metabolism. Mr. W. K. Slater, M.Sc., (1) completion of work on a correction of the value for the heat of combustion of glycogen, (2) determination of the molecular weight of glycogen, (3) partial supervision in the initial chemical work in the extraction of insulin, (4) investigation of cell mechanism under anaerobic conditions. Dr. Dorothy S. Russell, the relation of renal efficiency tests to the morbid anatomy and histology of kidneys. Mr. C. P. Stewart, M.Sc., (1) investigation of methods of isolation and chemical constitution of thyroxin, (2) continuation of research on liver perfusion of substances related to histidine. Mr. H. J. Channon, B.Sc., study of certain fundamental dietary factors in the nutrition of living organisms. Mr. William Smith, B.A., and Mr. Lewis B. Winter, B.S., investigations on general metabolism in health and disease, with special reference to metabolism of carbohydrates and the cause of diabetes. Miss D. B. Steabben, B.Sc., investigation of mechanism of response to injection of colloidal substances. Mr. C. S. Hicks, M.Sc., (1) investigation of the causation of goitre from a biochemical standpoint, (2) chemistry and pharmacology of substituents in the thyroxin molecule.

BRONCHIAL ASTHMA DUE TO MICE.

Dr. William Lintz,[1] clinical professor of medicine in the Long Island College Hospital, remarks that while emanations from all sorts of animals have been known to cause attacks of bronchial asthma, there is no case on record in which emanations from rats or mice have been the cause of such an attack. The following case which recently came under his observation is therefore the first example of mice being the cause of bronchial asthma. The patient was a married woman, aged 36, who had been suffering for the last seven years from typical attacks of bronchial asthma which occurred four or five times a month, mostly at night, only occasionally in the day-time, and chiefly from December to March. The attacks did not appear to bear any relation to food, weather, or the emanations from the cat, horse, or dog. All laboratory examinations and cutaneous allergic tests proved negative. No cause could be detected for the attacks, which were relieved by injection of adrenalin, until Dr. Lintz in examining the patient's premises was struck by the number of mouse-traps scattered about the house and learnt that the place was infested by rats and mice. It then occurred to him that the asthmatic attacks might be due to mice for the following reasons: (1) The attacks occurred from December to March, when the mice had left the fields for food and warmth in the house. (2) They usually took place at night, when the mice were running about the house. (3) When the patient stayed at her mother's house, a short distance away, in which there were no rodents, she was free from the attacks, which recurred as soon as she returned home and lay down in her bedroom. The correctness of the hypothesis was confirmed by exposing the patient to the emanations of a mouse without her knowledge, so as to exclude all psychical influence by placing the animal in a covered box and asking her to smell it at a time when she was perfectly free from asthma. Three minutes later she had a typical asthmatic attack associated with intense dermatitis. A very energetic campaign against the rodents in the house was then undertaken, and after removal of a few dead rats from beneath the patient's bedroom floor she remained free for three years from all attacks. The case proves, as Dr. Lintz remarks, that cases of bronchial asthma are pieces of research work, and often require a knowledge of the patient's environment before the problem can be solved.

---

[1] New York Medical Jour. and Medical Record, June 20th, 1923.

business meeting which concluded the programme some interesting cases were shown. These included cases under insulin treatment, shown by Dr. M. G. Thackrah, and a case of splenic enlargement for diagnosis, by Dr. A. M. Hutchison; a case of ovarian tumour simulating pregnancy by Dr. Frances Huxley; triplets, all with congenital hearts, by Dr. Helen Ingleby; and a case of mental deficiency with catatonia in small child by Dr. E. M. Pickard. Miss E. C. Lewis showed specimens of double ureter attached to a kidney with partial hydronephrosis, ureteric calculi, and pyelograms, while Dr. Hilda Whittingham had on view interesting slides of tumours of doubtful malignancy. These absorbing side-shows, while leading to much valuable discussion, were not allowed to detract from the holiday atmosphere of an afternoon almost in the country, for though easily accessible from central London the hospital appears to be surrounded by much open space. Altogether it was a most cheerful function. Dr. Louisa Martindale, supported by Lady Briscoe and Dr. Amy Sheppard, expressed the thanks of the Association to the medical and nursing staff for their hospitality, and more than one guest was heard to hope that the opening of the new surgical block, now in process of construction, would give occasion for another medical garden party at the South London Hospital for Women.

IS REINFECTION OF TUBERCULOSIS FROM WITHIN OR FROM WITHOUT?

COULD this question be definitely answered, one way or the other, the problems of tuberculosis, notably those concerned with prophylaxis, would be greatly simplified. If the Andvord-Römer hypothesis is correct, and the active pulmonary tuberculosis of adult life is merely the final stage of a long and consecutive train of events beginning with infection in childhood, the adult who gives a positive tuberculin reaction has little to fear from contact with sputum-positive cases of tuberculosis. To most rules there are exceptions, and in his latest communication Dr. K. Andvord has clearly pointed out that he does not regard the risk of exogenous infection among adults as perfectly negligible. Dr. Braeuning,[1] of Stettin, seems, however, to have come to the conclusion that exogenous reinfection is not merely of occasional, but of common occurrence. His opinions are founded on statistical observations which, though open to criticism from several points, are exceptionally interesting and instructive. Several lines of research were followed. First he took stock of the 244 families in Stettin, in each of which there was a case of open tuberculosis notified in 1919. There were 1077 persons in these families—i.e., there were 833 contacts. What, he asked, was the incidence of open tuberculosis among these contacts during 1919, 1920, and 1921 as compared with that of the whole population of Stettin? The answer was illuminating. Among the contacts there were 27 new cases of open tuberculosis in the three years under discussion—i.e. 32·4 per thousand. In the same period in the general population this ratio was only 5·4 per thousand. In other words, the incidence of new cases of open tuberculosis among the contacts was between five and six times as high as in the general population. Dr. Braeuning discusses various sources of error in his comparison, and he notes that as these errors did not operate only on one side, they tended to neutralise each other, and were in any case negligible in view of the striking differences in the two tuberculosis rates. He has, however, omitted to mention one important factor or possibility which might bring the Andvord-Römer hypothesis in line with his own findings. The 27 persons who developed open tuberculosis within a few years of the notification of an earlier case in the same house may have been exposed to the same infection many years earlier—in childhood. If, for example, a man, aged 25, develops pulmonary tuberculosis in 1919, and his sister, aged 23, develops the disease in 1920, and it transpires that their mother died of pulmonary tuberculosis when they were still infants, who shall say that the sister contracted the disease from her brother in 1919 and not from her mother two decades or more earlier?

Dr. Braeuning was not, however, satisfied with only one line of research. He grouped his contacts in four classes, according as the hygienic conditions under which they lived were good, bad, or somewhere between these extremes. There were 218 persons living under good conditions, save that they were in contact with a case of open pulmonary tuberculosis. Only 1·3 per cent. of these contacts developed open tuberculosis in the period 1919–21. But of the 122 contacts living under the most unhygienic conditions, as great a proportion as 4·9 per cent. developed open tuberculosis in the same period. At a casual glance these figures certainly suggest that particularly favourable opportunities for exogenous reinfection explain the marked differences in the number of new cases of tuberculosis in the two classes. But the matter is not really so simple. For contacts living in poverty, dirt, and squalor are subject to many noxious influences besides that of massive infection, and these other influences cannot be dismissed as negligible. The contact living in hygienic surroundings is probably receiving better pay, is less overworked and underfed than his fellow-contact in a slum. And, it may be argued, he is comparatively immune, not because infection is less massive in a clean than in a dirty home, but because his opportunities for maintaining acquired immunity are comparatively great. A third line of research open to the same criticism as the first was an inquiry by Dr. Braeuning of 100 patients suffering from open tuberculosis as to their having been in contact with cases of pulmonary tuberculosis shortly before their own disease developed. The same question was addressed to 100 non-tuberculous patients. A history of exposure to infection was obtained between two and three times as often (2·7 to be exact) in the first as in the second class. Dr. Braeuning argues that all his lines of research converge on one point; exogenous re-infection of tuberculosis is very common. It may be. But valuable as Dr. Braeuning's researches are, it cannot be claimed that they are the last word in this matter and a complete answer to the heading of this annotation.

A TRIBUTE TO THE MAYO CLINIC.

AT a Congregation of Leeds University, held on July 13th in the School of Medicine, the honorary degree of Doctor of Science was conferred by Sir Michael Sadler upon Dr. W. J. Mayo of Rochester, Minnesota. In presenting Dr. Mayo, the Dean of the Faculty of Medicine, Prof. J. K. Jamieson, spoke as follows:—

> The remarkable institution called the Mayo Clinic in Rochester, U.S.A., emanates from the brains of the Mayo family, father and sons. Even were it permissible to describe it in a degree oration, that could not be done in the Latin or English forms in use in our universities; it would require the happy amœbic pseudopodia of ancient Greek or the still developing collateral anastomoses of the American language to give a true idea of the development of the institution.
>
> It stands now as a colossal monument of organising ability founded on the sure rock of tireless work carried on with faith and enthusiasm. It is a notable illustration of what may be done by devoted coöperation. As there is nothing new under the sun one desires to seek its prototype in history. If there be a prototype it is in the Temple of Æsculapius at Kos. We do not know that this ever contained more than the spirit of a genius, and the Mayo Clinic fortunately possesses the body as well; but imagination allows us to draw a picture illustrating the resemblance. Were some catastrophe to dismember civilisation it is quite possible that Rochester would become the second Kos. Therein we might find the buildings tenanted by priests clad in white vestments and masks performing a ritual reminiscent of the surgery of the early twentieth century, and receiving from the faithful tithes of the flocks and herds and corn and oil, and—may we say—wine.
>
> The creation and development of an organism which is a fountain of progress in surgery flowing all over the world is surely good reason for our desire to honour its Director;

---

[1] Beitr. z. Klin. d. Tuberk., 1923, Bd. lv., Hft. 2.

does no more than repeat experiments and confirm results already amply established, perhaps by workers in Hong-Kong, Christiania, or some South American republic, and printed in full in the native language of the investigator. Most scientific libraries have reliable indices whereby the titles of relevant papers may be found, but the periodical itself may not be among those taken in at the library, and the librarian may be at a loss to suggest where it may be inspected. To fill this need Prof. R. T. Leiper, F.R.S., some time ago suggested to the British Medical Association the production of an index or guide to the libraries in which the very numerous scientific periodicals can be found, and he has now, with the collaboration of Mrs. H. M. Williams and Miss G. Z. L. Le Bas, M.Sc., prepared such an index. The list prepared by Prof. Leiper and his colleagues serves to indicate where much of the periodical literature of medicine and the allied sciences may be consulted, not only in London, but also in Cambridge, Oxford, Edinburgh, Glasgow, Liverpool, and Manchester, and has been compiled from library catalogues and from lists made personally by the compilers. It reveals the important fact that the National Library in the British Museum contains also the most extensive and representative series of foreign medical and scientific periodicals in Britain. The book is being published this week at the price of 10s. 6*d.*, and will be obtainable through any bookseller, or at the offices of the British Medical Association, 429, Strand, London, W.C. 2.

THE RELIEF OF LEPROSY IN THE BRITISH EMPIRE.

ON July 12th, at a meeting held in the India Office under the chairmanship of Lord Chelmsford, it was decided to form a British Empire Leprosy Relief Association. Despite the imperfect statistics available in this connexion, the British Empire is acknowledged to contain more known lepers than any other political unit, but far less is done for these sufferers, in proportion to their numbers, within the Imperial boundaries than in the United States. Less than 5 per cent. of British-governed lepers are now cared for in any way, and of that percentage only a small proportion are receiving the latest form of treatment —a fact mainly due to the poverty of India, tropical Africa, and the West Indies, the countries most affected. The present situation in India is briefly indicated in another column in connexion with the work of the Mission to Lepers.[1] An influential general committee, and a strong executive committee, with subcommittees, were appointed to draw up plans for action by the association, whose establishment and promised activity will be a source of great satisfaction to all who realise the extent of the leper problem in the Empire, and the hope given by recent advances in the treatment of the disease.

ANNUAL MEETING OF THE B.M.A.

THE annual meeting of the British Medical Association opens to-day, Friday, July 20th, at Portsmouth, when Sir William Macewen, the President, will vacate office in favour of the President-Elect, Mr. C. P. Childe, senior surgeon to the Royal Portsmouth Hospital. The time chart of the meeting follows precedent in that the opening and three following week days will be taken up by the annual Representative Meeting, while the Scientific Sections will meet on Wednesday, Thursday, and Friday, July 25th, 26th, and 27th. The annual dinner of the Association will take place at the City Town Hall on July 26th. The exhibition of surgical appliances, foods, drugs, and books will be open during next week, the closing day of which—viz., Saturday, July 28th—has been set apart for excursions to places of interest in the neighbourhood. The hon. local general secretary is Mr. C. A. Scott Ridout, of St. Emo, Clarendon-road, Southsea.

THE house and library of the Royal Society of Medicine will be closed for cleaning and repairs during the whole of August.

Sir Napier Burnett's fourth annual report on the Voluntary Hospitals in Great Britain (excluding London) has just been issued. In an introductory note Sir Arthur Stanley calls attention to the wonderful improvement in financial position shown by these hospitals in 1922, when the ordinary income of 666 hospitals only fell short of ordinary expenditure by £75,000. "Mass contribution" has been successfully called in to redress the balance of the old individual donor who has dropped out. The curious fact is revealed that out of a total of 5179 beds in "cottage hospitals" 2000 were vacant during 1922. Mention is made of increasing laboratory accommodation in hospitals throughout the country and of the establishment by the Red Cross Joint Council of a central bureau of information on hospital matters.

ROYAL MEDICAL BENEVOLENT FUND.

AT the meeting of the Committee on July 3rd 25 cases were considered and £262 voted to 17 applicants. The following is a summary of some of the cases relieved:—

Daughters, aged 51 and 46, of M.D. St. Andrews who practised in Hampshire and died in 1878. Through the death of a brother, whose pension ceased at his death, these ladies are in somewhat straitened circumstances, having had to find the money for the brother's funeral. After his estate is cleared up they do not expect their income to exceed £30 per annum each. The elder sister received £30 from sewing, and the younger £20 as a journalist. The rent amounts to £1 per week. Voted £20.

Daughter, aged 54, of M.R.C.S. Eng. who practised at Mold and died in 1871. Applicant was a school nurse, but since May, 1922, she had pneumonia, and has not been able to carry on her work and is now suffering from degeneration of the cerebellum. Her brother will allow her 5*s.* per week and friends have given her £5. She receives board and lodging in return for light household duties. Voted £18 in 12 instalments.

Widow, aged 63, of M.R.C.S. who practised in Cheltenham and died in 1920. Through rheumatic fever and congestion of the lungs applicant has only earned £40 during the last 12 months. Youngest son was studying medicine, but owing to death of father had to give it up and take a post in a bank. Applicant has had an offer to go to B.C. to look after some children, but has not the means to go. Voted £5.

Widow, aged 49, of M.R.C.S. Eng. who practised in Wales and died in 1910. A brother-in-law has aided the applicant to the extent of £15 per annum, but he has now retired and is unable to continue this assistance. This money was used to pay the eldest daughter's travelling expenses to and from school, and the applicant asks the Fund if they can make a grant for this purpose. Voted £10 in two instalments.

Subscriptions may be sent to the honorary treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos-street, Cavendish-square, London, W. 1.

INDEX TO "THE LANCET," VOL. I., 1923.

THE Index and Title-page to Vol. I., 1923, which was completed with the issue of June 30th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

SMALL-POX IN ENGLAND AND WALES.—During the week ending July 7th 145 cases of small-pox were notified (the largest number this year) in England and Wales, the distribution being as follows: Derbyshire 15 (Alfreton 1, Long Eaton 13, Shardlow R.D. 1); Durham 1 (Stockton-on-Tees "doubtful"); Gloucestershire 93 (Gloucester 91, "including 18 cases of chicken-pox rediagnosed as small-pox," Gloucester R.D. 1, Stroud R.D. 1); Lancaster 1 (Colne); Nottinghamshire 22 (Kirkby-in-Ashfield 8, Sutton-in-Ashfield 14); Westmorland 1 (Windermere "doubtful"); Wilts 1 (Swindon); Yorks West Riding 8 (Huddersfield 1, Bentley-with-Arksey 1, Doncaster 1, Doncaster R.D. 5); Flintshire 1 (Flint); Monmouth 2 (Rhymney 1, Risca 1).

---

[1] See p. 153.

ON SMALL-POX DIAGNOSIS.

THE recent spell of tropical weather, which lasted continuously for nearly a fortnight, has synchronised with some remarkable cases of chicken-pox, of such a nature that further notes may be helpful to those faced with similar cases should the hot weather recur. The striking feature of these cases of chicken-pox has been the profuseness of the rash upon certain sunburnt surfaces such as the forearm and neck; and also the extreme severity of the rash, so that the secondary fever has reached a temperature of 103° F. in one and 104° in another of the cases. It seems that it is the flushed, sweaty, and irritated condition of the skin which has led to some of these severe rashes. They form good illustrations of the value of attaching due weight to all the evidence. One of these cases may be quoted:—

H. B., male, aged 14, was covered from head to foot with a most copious rash, the total number of his spots amounting to probably at least 1500. An approximate count of his spots showed as follows: Right hand, palm 5 faint spots, back of hand 50 to 70, right forearm 100 to 150, right arm 150 to 200. Left hand, palm 3 faint spots, back of hand 40 to 60, left forearm 60 to 80, left arm 100 to 140. Face 200 to 300, front of chest and abdomen 400 to 500. In the left armpit were 20 to 30 spots and in the right armpit 15 to 25; on the sole of the right foot about 10 to 20 spots, left sole 8 to 12 spots. A temperature of 104° F. was reached during the suppuration of the pocks. It was noteworthy also that at the onset, but for the occurrence of the spots, neither the patient nor his mother would have noticed any illness in him at all. The lesions, notably on the trunk, were superficial with crenate outline, irregularly oval, the long axis running parallel to the natural folds of the skin; in fact many of them individually were precisely typical of chicken-pox, the only unusual feature being their extreme abundance. They had matured at a much more rapid rate than would have been possible in variola. The boy had been vaccinated in infancy and showed four plain scars. There had been chicken-pox among some vaccinated children in the house. Another striking case was that which occurred in two children who recently had been spending a holiday at the seaside and whose legs had been so scorched by the sun that there was mild acute sunburn. The rash of chicken-pox had picked out these children's irritated surfaces in a very remarkable degree; here again the diagnosis was rendered perfectly clear by the concomitant signs. In yet another case the neck and upper part of the back had been remarkably picked out by the rash of chicken-pox, owing presumably to that area having been partly sun-scorched and partly chafed due to the clothes bearing on a perspiring surface.

While the rash of both small-pox and, to a less degree, of chicken-pox favours irritated surfaces, a more intense degree of hyperæmia may be required in chicken-pox than in small-pox to bring out this peculiar phenomenon. The suggestion is worth following up should the heat continue.

A Case of "Mild Small-pox" as at Present Prevalent in Gloucestershire.

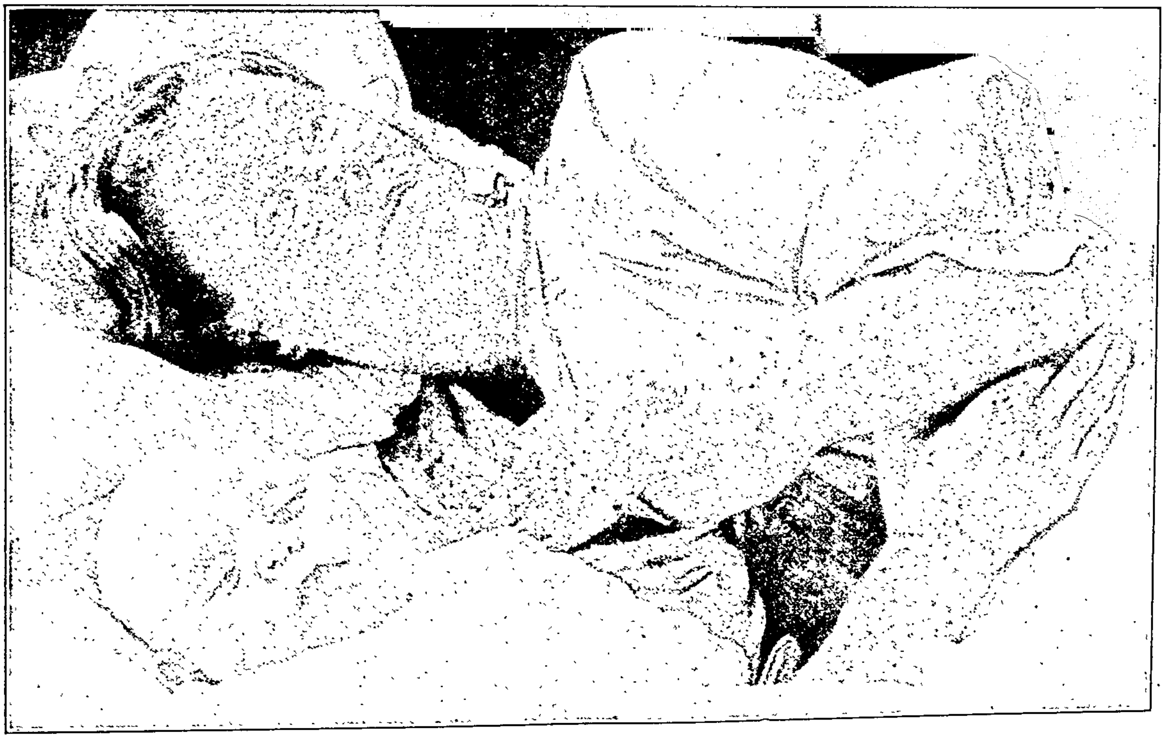

Photo by H. C. Leat, Gloucester.

By the courtesy of the Ministry of Health and with the permission of the patient we reproduce herewith a photograph of Mrs. A. and baby taken at Gloucester on June 26th and showing the characteristic eruption of small-pox with its well-marked centrifugal distribution on face and arms. Mrs. A., aged 26, was notified as suffering from small-pox on June 15th and admitted to hospital on the same day. The onset of prodromal symptoms was on June 9th with headache, vomiting, and pains all over; the rash appeared on June 12th, profuse and coherent on face, arms, and legs, giving rise for four days to a secondary temperature of 100°–101° F. Desquamation was practically complete on July 16th. At the time of admission to hospital Mrs. A. was nursing a baby who accompanied her. The baby was successfully vaccinated in four places on the arm on June 16th and has remained free from infection. Mrs. A. continued to nurse the baby during her illness.

HELP IN THE SEARCH FOR REFERENCES.

THE time and physical energy wasted in the search for references by anyone engaged in the pursuit of scientific investigations disheartens on occasion the most zealous worker. If he neglects even one possible source of information, which may be specially difficult of access, he may be punished by finding just before or even after publication that his research patient makes an effort to open his bowels each morning after breakfast. If he fails, an ounce of glycerine is injected. Should this prove successful, the next morning one drachm of the ounce is replaced by water, and on successive days the strength of glycerine is steadily reduced till eventually an ounce of water with no glycerine is used. By this time the patient is generally cured, but it is occasionally necessary to continue with the water in diminishing quantity for a few more days. Sometimes glycerine does not act satisfactorily. Graduated water enemas should then be substituted; if a pint is found to act well, the amount used should be reduced by one ounce every day till no more injections are required.

Massage and Exercises.

In severe cases of colonic constipation massage is of the greatest value. The first treatment should be given after the patient has had an opaque meal; he lies on the X ray couch under the fluorescent screen, so that the masseur can be shown the exact position of the colon, the part chiefly affected, and what manipulations are required to influence it. In dyschezia, and in some cases of colonic constipation, massage is very useful for improving the condition of the abdominal muscles. Swedish exercises are still more valuable. In the numerous cases of dyschezia, which are due to weakness of the muscles of the abdominal wall and pelvic floor, daily exercises for some weeks produce excellent results. The muscles of the pelvic floor should not be forgotten, as in women who have borne children weakness of the levator ani muscle is a very common factor in the production of dyschezia. The patient should be taught to draw in her anus, just as if she were trying to prevent a liquid stool from being evacuated; she then relaxes. This exercise should be repeated 30 times every morning and evening whilst lying in bed. Not only does it help to cure the dyschezia, but it quickly overcomes minor degrees of rectal and vaginal prolapse.

Regular exercise in the open air is very beneficial. Slight constipation can often be cured by inducing a man to walk a couple of miles on his way to business; though unable to open his bowels directly after breakfast, he will have no difficulty on arriving at his office. A man who is busy during the week should take as much exercise as possible on Saturday afternoon and on Sunday, and he should have adequate annual holidays to prevent over-fatigue, both mental and physical; this is an important factor in many cases of habitual constipation.

Surgery.

There is no surgery of habitual constipation. Ileo-sigmoidostomy, and partial and complete colectomy are—or should be—dead. Grave organic disease leading to intestinal stasis is not included under "habitual constipation"; it calls, of course, for operation. But in the absence of this, surgery is as much out of place in disorders of the colon as it is in functional disorders of the stomach.

IMPERIAL CANCER RESEARCH FUND.

ANNUAL REPORT.

THE twenty-first annual report of the Imperial Cancer Research Fund, under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England, was submitted at the annual meeting of the Fund held on July 17th, the Duke of Bedford, President of the Fund, being in the chair.

Honorary Treasurer's Report.

Sir George Makins, honorary treasurer, in his report, stated in the past year subscriptions to the Fund had amounted to £951 11*s.* 6*d.*, being an increase of £447 1*s.* 0*d.* on the previous year, and several legacies of considerable amount had been received, totalling £3,675 15*s.* 6*d.* The amount of £4000 promised by Mr. and Mrs. Todman last year has been received, and in addition, through the munificence of an anonymous benefactor, the Alice Memorial Fellowship, amounting to about £500 per annum, had been endowed. It was earnestly to be hoped that supporters would continue to contribute to the Imperial Cancer Research Fund, as by so doing they would be supporting researches which have proceeded without cessation since the year 1902.

Secretary's Report.

It was announced that the lease of the farm hitherto occupied by the Fund expires in September, and that a portion of the land acquired by the Medical Research Council at Mill Hill has been leased from the Council for 21 years. It is hoped that the close association between the two staffs in the laboratories to be built at Mill Hill may be of considerable benefit to scientific investigation.

The conditions agreed on for the prize offered by Lord Atholstan for the discovery of a cure for cancer are set out, and include a provision that all applicants must in the first place satisfy a recognised medical faculty or a leading medical society in his or her own country (*a*) that there is some scientific basis to justify experimental investigation of the professed cure, (*b*) that any cases said to be successfully treated were, in fact, cases of cancer, and one that applicants must disclose to the medical faculty or medical society investigating the professed cure its nature and ingredients, and the method of its preparation. Lord Atholstan's grant to the Fund for research has been utilised by the appointment of Dr. A. M. Begg to carry out an investigation on the subject of the infective sarcomata (dogs and fowls) with a view to defining the difference, if any, between them and true neoplasms. In March last the liberal offer of an anonymous donor to found an "Alice Memorial Fellowship" for cancer research under the auspices of the Imperial Cancer Research Fund was accepted, and Dr. Marshall Findlay has been appointed the first "Alice Memorial Fellow." The list of scientific papers published by members of the staff during the year is an imposing one. Material from the laboratory has been sent to 13 workers at home and abroad. A considerable portion of the annual report is devoted to an account of the negotiations between the executive committee of the Fund and the committee of the British Empire Cancer Campaign. When the Fund was first approached early in April of this year by the promoters of the Campaign with a view to its coöperation, a resolution was passed that before the Imperial Cancer Research Fund agrees to coöperate with the British Empire Cancer Crusade in organising and carrying out cancer research, it must be satisfied as to the conditions to be adopted in allocating the money to be raised by the appeal. At another meeting on April 18th, as the result of further correspondence, it was agreed that the Fund did not see its way to associate itself with the cancer crusade unless

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXIX.—THE TREATMENT OF HABITUAL CONSTIPATION.

The general public usually believes that it is capable of diagnosing and treating habitual constipation for itself. Consequently a patient rarely comes for advice who is not already under treatment prescribed by himself or his friends. In many cases his symptoms are due to his pills rather than his constipation, and it is impossible to make an accurate diagnosis, upon which satisfactory treatment must depend, until he discontinues to use his remedies for a few days.

My investigations with the X rays between 1907 and 1909 led me to classify habitual constipation broadly into two forms: (1) colonic constipation, in which there is delay in the passage of fæces from the cæcum to the rectum, and (2) dyschezia, or inefficient defæcation, in which the patient has lost the power of expelling the contents of the rectum. In colonic constipation the cæcum and ascending colon, or less frequently some other part or the whole of the colon, is found on abdominal palpation to be distended with fæces, but digital examination shows that the rectum is empty. On the other hand, in dyschezia the rectum is full, although the patient is generally unaware of this and is quite incapable of emptying it; no accumulation of fæces is present in the rest of the bowel, except sometimes in the pelvic colon. An accurate diagnosis can only be made with the aid of the X rays, which show exactly what part of the colon is involved in colonic constipation, whilst in dyschezia they show that the passage as far as the rectum is normal in rate. In my experience the two forms of constipation are about equally common, many of the most severe cases being examples of dyschezia. Colonic constipation, if untreated, is much more likely to give rise to toxic and other symptoms than dyschezia, which generally leads to nothing more than inconvenience and slight local discomfort, unless it is treated by aperients and other unsuitable measures, which themselves give rise to toxæmia by irritating the colon and keeping it full of fluid fæces, which form an excellent medium for bacterial activity.

In general colonic constipation requires treatment by diet, and, in severer cases by drugs and massage, and dyschezia by persuasion and exercises, and, in severer cases, by graduated enemas. In both attention to the

Hygiene of the Bowels

is essential. Constipation can generally be prevented by proper attention to the hygiene of the bowels, and most mild cases, especially of dyschezia, can be cured in this way. The individual should have a cold bath on getting up, or at least a cold douche over the abdomen and back after a warm bath, and should not breakfast in bed. He should rise sufficiently early to allow plenty of time for his visit to the water-closet, which he should never fail to make after breakfast, even if he feels no desire to open his bowels. If the bowels do not act, he should try again after a walk or after lunch or dinner. The water-closet should be well ventilated, but not too cold. The seat should be low enough to allow a crouching position to be adopted; if necessary, a footstool should be provided; in severe dyschezia a bed-pan should be placed on the floor, over which the patient can squat. Too much attention should not be paid to the subject; the patient should realise that "his bowels were made for man, not man for his bowels." For many one action on alternate days is sufficient; occasionally even longer intervals are normal, and I have known very healthy people with unusually greedy colons, who were never well if their bowels opened more than once a week.

Diet.

All cases of habitual constipation are benefited by taking a suitable diet, and in slight cases this should make the use of drugs unnecessary. The guiding principle is to give plenty of fruit and green vegetables, which leave an adequate residue to act as a mechanical stimulus to intestinal activity, and in most cases also contain chemical stimulants to peristalsis. It is a good plan to take ten or a dozen stewed prunes as well as jam or marmalade for breakfast every morning, and fruit, either raw or stewed, and green vegetables either cooked or in salad, both at lunch and dinner. A diet of this kind is particularly necessary in cases of habitual constipation caused by a greedy colon, in which the absorptive power of the bowels is developed to an abnormal extent. In such cases the addition of a teaspoonful or more of powdered agar-agar to porridge, potatoes, or stewed fruit at each meal is useful, as it expands by the absorption of moisture, and, being almost completely indigestible, adds bulk to the otherwise insufficient fæces.

Drugs.

For colonic constipation a drug is required which stimulates the colon without unduly irritating it, and the dose employed should be one which produces a single formed stool each morning. In my experience senna is, as a rule, the most satisfactory, and it has the great advantage that the patient can accurately regulate the dose he takes from day to day. In a case of moderate severity seven senna pods should be tried the first evening. The number can then be increased or diminished according to the result obtained, and when the right dose is discovered the patient should make frequent attempts to reduce it by one pod every other night. The pods should be soaked in cold water for three hours, and the infusion should be drunk either at dinner-time or on going to bed. Hot water extracts a griping element from the pods, which is absent from the cold infusion. If any griping still results, one minim of tincture of belladonna should be added to the infusion for each senna pod.

Liquid paraffin passes through the alimentary canal without undergoing any change. It is quite inert, but as Neville Wood, who introduced it to the profession in 1899, first pointed out, it makes hard fæces soft, and so causes their passage through the bowel and their final expulsion from the rectum to be comparatively easy. It is therefore valuable in dyschezia as well as in colonic constipation. It can be used in addition to any other methods of treatment; if, for example, half an ounce is taken after breakfast and after dinner, the dose of senna required in a case of colonic constipation is much reduced.

Enemas.

In the majority of cases of habitual constipation there is a tendency for an accumulation of fæces to occur. If abdominal or rectal examination has shown that this is the case, the bowels should be thoroughly washed out before any other treatment is begun. In very severe cases of colonic constipation a douche should be given daily for two or three weeks, the quantity used being gradually reduced from an initial injection of a pint and a half. The efficacy of the treatment is greatly increased by having the colon massaged whilst the water is still present in it. The fluid should be run in at a pressure no greater than 18 inches, the quantity used should never exceed a pint and a half, and the tube should not be inserted more than two inches from the anus. The X rays have proved that fluid introduced in this way always reaches the cæcum unless organic obstruction is present, and that a tube introduced more than 4 inches—as with the old-fashioned "high enema" of the so-called Plombières treatment—simply curls round and round in the rectum and irritates its mucous membrane, as it is almost impossible for it to pass round the pelvic-rectal flexure into the pelvic colon.

If re-education alone fails to cure a case of dyschezia, graduated glycerine enemas should be tried. The

The report showed that the Fund continued to pursue its considered policy of coöperation with the workers in different laboratories coupled with the interchange of material; such coöperation and coördination must, however, be voluntary and could not be forced on the workers.

The President then proposed, and Dr. Sidney Martin, F.R.S., seconded, the adoption of the report. Sir William Church was elected a Vice-President on his resignation of the chairmanship of the executive committee.

PROVIDENT ASSOCIATION FOR HOSPITAL AND ADDITIONAL MEDICAL SERVICES.

REPORT FOR PERIOD NOV. 1ST, 1921–FEB 28TH, 1923.

THE National Provident Association for Hospital and Additional Medical Services, by arrangement with the several interests concerned, was established in London on Nov. 1st, 1921, and £55 was spent in a few newspaper advertisements. When 2315 members were rapidly enrolled it was decided to treat the first year's working as an experiment and not seek further members until the Association was incorporated and put on a permanent basis. The amount received in subscriptions was £1770.

Objects of the Scheme.

The object of the Association was to induce people, while in health, to make provision for the time of serious illness and to enable its members to obtain such services other than ordinary—i.e., general practitioner—treatment as they might require in illness without additional charge, and the services provided included inter alia: the ordinary services of a coöperating hospital, consultations at home in *serious illness*, the services of visiting nurses, treatment at the Radium Institute when required, and the use of ambulances.

It was decided: (1) That the scheme should be provident—i.e., that the subscriptions should be of such amount as would in the aggregate meet the cost of the services required without encroachment upon charitable funds. (2) That the administration should be in the hands of a neutral body which should impartially guard the interests of all concerned. (3) That the work of the general practitioner should not be interfered with, but that, as far as possible, he should be helped in his work for the benefit of those of his patients who were members of the Association. (4) That all benefits under the scheme should be obtained on the recommendation of the private medical attendant of the member. (5) That there should be no interference with the existing rules or routine and work of the hospitals or of any other bodies concerned. (6) That the income limit prescribed for members should, as nearly as possible, be in accordance with the income limits of those ordinarily admitted to hospital treatment.

An Experimental Year.

Arrangements had also been made for group membership on the same principles at a lower rate of subscription which would cover the hospital services only, but this branch was transferred to the Hospital Saving Association, who also took over and carried through the incorporation which had been applied for to the Board of Trade. The income of £1770 for the period was allocated beforehand as follows, viz.:

		£	s.	d.
To nursing	3/40ths	132	15	0
To ambulances	1/40th	44	5	0
To consultations and radium	6/40ths	265	10	0
To coöperating hospitals ..	26/40ths	1150	10	0
To administration	3/80ths	66	7	6
To reserve	5/80ths	110	12	6

Of the 2315 members 56, or 2·4 per cent., were in-patients during the year and their average stay in hospital was 23·8 days, while 258, or 11 per cent., were treated as out-patients or received special services, such as X ray, massage, electrical treatment, laboratory investigations, &c., the returns showing a total of 1378 attendances, or an average of 5·4 per patient. The payments to coöperating hospitals amounting to £1150 10s. are equivalent to a payment of £5 7s. 1*d.* a week for each in-patient and of 10s. for each out-patient, and include any provision which the hospitals may have made for a payment to general medical staff funds. Consultations in the patients' own homes were paid for by a fee of 3 guineas for each consultation. The amount allocated to nursing has been paid in full, but after paying for all the services rendered during the period, a balance of £406 remains in hand upon the other accounts, after all liabilities to members have been finally discharged.

Change of Name and Incorporation.

The committee feel that the year's experiment has fully justified their anticipations, and the statistical results encourage them to hope that in a system of provident coöperation lies the solution to the financial problem of the voluntary hospitals.

The report is signed by Sir Arthur Stanley, Lord Dawson of Penn, Mr. W. McAdam Eccles, Sir Alan G. Anderson, and Dr. J. F. Gordon Dill (hon. secretary), members of the Executive Committee.

On May 9th, 1923, the Association was registered under the Companies Acts, as a company not for profit, under the title of the British Provident Association for Hospital and Additional Services, the signatories to the memorandum and articles of association in addition to those named above being Lord Knutsford and Captain J. M. Gordon Dill.

RESEARCH IN TROPICAL DISEASE.

IV. THE WELLCOME BUREAU OF SCIENTIFIC RESEARCH.

THIS Bureau was founded towards the end of 1913 by Mr. Henry S. Wellcome, who, in 1902, had presented the laboratories bearing his name to the Sudan Government, and who has, in many directions, evinced his keen interest in tropical research. For the first few years of its existence the Bureau was housed at 10, Henrietta-street, Cavendish-square, but, subsequent to the war, removed to the premises it now occupies at 26, Endsleigh Gardens alongside the London School of Tropical Medicine, with which it has the privilege of coöperating in certain directions. From the start it has been under the direction of Dr. Andrew Balfour, formerly in the Education Department of the Sudan Government, director of the Wellcome Tropical Research Laboratories, Gordon Memorial College, Khartoum, and medical officer of health for that city.

The Bureau exists not only for purposes of research, more especially in connexion with tropical medicine and hygiene, but also with a view to supplying information gratis to medical men, sanitary administrators, and others interested in these subjects. From small beginnings it rapidly progressed, and though for a time its routine activities were curtailed by the war, the whole of its scientific staff being employed on military duties in one capacity or another, and for the most part abroad, work was resumed thereafter and has developed in various directions. There is now a deputy director, Lieut.-Colonel G. E. F. Stammers, R.A.M.C. (retd.), and departments of protozoology, pathology, bacteriology, helminthology, and entomology have been formed. In connexion with the last named, Mr. Wellcome has established a field laboratory at Wisley, Surrey, where work is carried out on mosquitoes and other insects of medical interest. An important feature of the Bureau is the large teaching and research museum of tropical medicine and hygiene arranged on graphic and somewhat novel lines; of which Dr. S. H. Daukes is the curator. This museum is freely open to all who may care to visit it, and arrangements are made whereby lecturers may bring their students and impart other cancer research institutions were invited to take part and to receive similar financial support. The Fund suggested that the following institutions should be invited to occupy a similar position in relation to the crusade—namely, the Cancer Hospital, the Middlesex Hospital, the Radium Institute, the Manchester Cancer Investigation, the Liverpool University Cancer Committee, the Glasgow Cancer Hospital, and the Marischal College, Aberdeen, the attitude of the Fund depending on that of the majority of these institutions. The Fund deprecated any appeal to the public based on the supposition that if large sums of money are provided a cure will be found at an early date. The committee of the British Empire Cancer Campaign did not at first (May 2nd) see their way to invite the bodies mentioned to appoint representatives, and consequently it was considered inadvisable by the executive committee that the Fund should participate in the Campaign.

Subsequently, as the result of further correspondence, numerous interviews, and an intimation that most of the institutions interested in cancer research above referred to had been invited and that some had agreed to join in the campaign, the executive committee on May 16th decided to appoint five representatives to the grand council of the Campaign. Since this time further difficulties have arisen, certain clauses in the Articles of Association of the Campaign, which had not previously been disclosed to the executive committee of the Fund, not meeting with their approval; but in view of the proposed modifications in the Articles of Association, including the formation of a scientific committee which shall advise on the allocation of funds for scientific research, it is believed that the Imperial Cancer Research Fund will be able to coöperate in the Campaign.

Speech of Chairman of Executive Committee.

The report of the Director, Dr. J. A. Murray, was well summarised by Sir William Church, chairman of the executive committee, in moving the adoption of the report. He said:—

Vitamin Deficiencies.—The laborious study of vitamin B and vitamin A deficiencies in which Dr. W. Cramer has been engaged for the last three years may now be considered as completed. Neither of these deficiencies, nor both combined, arrested the growth of cancer, even when pushed to a degree incompatible with life. The great adaptability of the cancer cell to changes in its environment frustrated the hopes which were aroused by the discovery of the profound influence of these food accessories on the growth of young animals. In the course of these researches a striking similarity was found between the effects of vitamin deficiencies and the damage produced by radium and X rays. The study of this relation was made possible by the close and friendly collaboration of Dr. Mottram of the Radium Institute.

Tissue Culture.—The improvement Dr. Drew has made in the methods of tissue culture outside the body have enabled him to add considerably to our knowledge of the factors which control the differentiation of tissues, and also of the mechanism of repair after injury. Using the growth of normal tissues in vitro as an indicator of the presence of active substances in the culture medium, he has proved that differentiation of epithelial cells is mainly controlled by the interaction of the connective tissues with them. When connective tissue cells are absent, the characteristic form and arrangement of the epithelial cells do not appear. The addition of connective tissue cells to an undifferentiated sheet of epithelial cells is quickly followed by typical differentiation. The process can be reversed, and repeated at will. The same holds good for cultures of transplantable new growths. Extremely undifferentiated mammary carcinoma can be turned in vitro into an adenomatous structure very similar to developing mamma. These results are a further step in the elimination of unimportant details from the cancer problem. Loss of differentiation when it occurs in cancer, is not a fundamental permanent feature as has long been supposed. It is superficial and may disappear without corresponding change in malignancy.

Repair of Injury.—The way in which injury sets repair agoing has been studied and throws an interesting sidelight on the growth of cancer. While embryonic tissues and tumours start growing at once when placed in a suitable culture medium, tissues from adults, even if young, only start growing after an initial delay which may be as long as 14 days. If adult kidney be ground up with saline solution and incubated for two hours and then filtered, the addition of the filtrate to the culture medium starts adult tissue growing at once. An extract of unincubated damaged kidney has no such power. An extract of undamaged rapidly growing carcinoma or sarcoma, however, is as active as the extract of incubated kidney. The cancer cells produce in the ordinary course of their existence substances which normal tissues elaborate only in response to injury.

Scientific Report.—A scientific report will be published in the autumn giving an account of these researches of Dr. Cramer and of Dr. Drew, as well as further observations by Dr. Murray on the difficulty met with when the attempt is made to produce a new carcinoma by tar painting in animals in which primary cancer has already appeared. The extension of Dr. Russell's work on carbohydrate metabolism of normal and cancerous tissues to the pentoses, and other papers, will also appear in it.

Statement of Progress Achieved.—As this is the last occasion on which I shall move the adoption of the annual report, I hope I may be permitted to occupy your attention a little longer with a brief statement of the progress achieved in the 21 years I have been chairman of the executive committee. When the Fund started cancer was generally believed to be a disease of civilised man. A parasitic causation was very widely believed in and those who regarded such a causation as unlikely in carcinoma were ready to admit its probability for sarcoma. We know now that cancer occurs in all races of mankind and in all vertebrate animals. The sarcomata have finally taken their place alongside the carcinomata as malignant new growths of connective tissue. Their frequency increases as age advances in the same way as the former, and sarcoma or carcinoma can be produced at will in laboratory animals according as the specific irritant is applied to connective tissue or to epithelium.

The rôle of chronic irritation in starting cancer has received experimental proof. Incidentally a rational explanation of the characteristic age incidence of cancer has been provided at the same time. The influence of heredity can be relegated with considerable certainty to the transmission of an enhanced sensitiveness to specific forms of irritation. The transplantability of new growths to healthy animals has made a careful study of their essential features possible. The phenomena of resistance to transplantation and tissue immunity with their curious limitations have been studied in detail. The explanation of the failure of these methods to furnish a means of treatment for cancer has made more precise our conception of the meaning of individuality in the higher animals. In all these investigations the Imperial Cancer Research Fund has played its part, in many of them a leading part. The present annual report shows that the working organisation is still vigorous and competent, and in laying down the duties of chairman of the executive committee I wish the Fund a successful future with confidence.

President's Speech.

The President said he was in complete agreement with the attitude taken by the executive committee, with reference to coöperation with the British Empire Cancer Campaign.

The President understood that a subcommittee appointed by the grand council of the Campaign had decided to make certain recommendations for embodiment in the Articles of Association, including the appointment of an advisory committee to include members nominated by the Royal Society and by the Medical Research Council in joint consultation. In the event of these modifications being carried out they would secure the confidence and coöperation of bodies engaged in cancer research, including the Imperial Cancer Research Fund, because in their opinion the future administration of the Campaign would then be guided by those whose knowledge would enable the best use to be made of all funds available. It was obvious from letters and articles which appeared from time to time in the press that incredibly little was known of the work that had already been done by this Fund and by other research bodies in this country and abroad—for instance, the information regarding cancer collected by the Imperial Cancer Research Fund relating to the disease in native races throughout the empire and of its occurrence in all species of the animal kingdom. For this reason it would seem to be essential that the administration of the Funds of the Campaign should be in the hands of those who know what experimental work has already been done, and what information on the subject has already been accumulated. By these means useless repetition would be avoided and public money used to the best advantage.

The report showed that the Fund continued to pursue its considered policy of coöperation with the workers in different laboratories coupled with the interchange of material: such coöperation and coördination must, however, be voluntary and could not be forced on the workers.

The President then proposed, and Dr. Sidney Martin, F.R.S., seconded, the adoption of the report. Sir William Church was elected a Vice-President on his resignation of the chairmanship of the executive committee.

PROVIDENT ASSOCIATION FOR HOSPITAL AND ADDITIONAL MEDICAL SERVICES.

REPORT FOR PERIOD NOV. 1ST, 1921–FEB 28TH, 1923.

THE National Provident Association for Hospital and Additional Medical Services, by arrangement with the several interests concerned, was established in London on Nov. 1st, 1921, and £55 was spent in a few newspaper advertisements. When 2315 members were rapidly enrolled it was decided to treat the first year's working as an experiment and not seek further members until the Association was incorporated and put on a permanent basis. The amount received in subscriptions was £1770.

Objects of the Scheme.

The object of the Association was to induce people, while in health, to make provision for the time of serious illness and to enable its members to obtain such services other than ordinary—i.e., general practitioner—treatment as they might require in illness without additional charge, and the services provided included inter alia: the ordinary services of a coöperating hospital, consultations at home in serious illness, the services of visiting nurses, treatment at the Radium Institute when required, and the use of ambulances.

It was decided: (1) That the scheme should be provident—i.e., that the subscriptions should be of such amount as would in the aggregate meet the cost of the services required without encroachment upon charitable funds. (2) That the administration should be in the hands of a neutral body which should impartially guard the interests of all concerned. (3) That the work of the general practitioner should not be interfered with, but that, as far as possible, he should be helped in his work for the benefit of those of his patients who were members of the Association. (4) That all benefits under the scheme should be obtained on the recommendation of the private medical attendant of the member. (5) That there should be no interference with the existing rules or routine and work of the hospitals or of any other bodies concerned. (6) That the income limit prescribed for members should, as nearly as possible, be in accordance with the income limits of those ordinarily admitted to hospital treatment.

An Experimental Year.

Arrangements had also been made for group membership on the same principles at a lower rate of subscription which would cover the hospital services only, but this branch was transferred to the Hospital Saving Association, who also took over and carried through the incorporation which had been applied for to the Board of Trade. The income of £1770 for the period was allocated beforehand as follows, viz.:

		£	s.	d.
To nursing	3/40ths	132	15	0
To ambulances	1/40th	44	5	0
To consultations and radium	6/40ths	265	10	0
To coöperating hospitals ..	26/40ths	1150	10	0
To administration	3/80ths	66	7	6
To reserve	5/80ths	110	12	6

Of the 2315 members 56, or 2·4 per cent., were in-patients during the year and their average stay in hospital was 23·8 days, while 258, or 11 per cent., were treated as out-patients or received special services, such as X ray, massage, electrical treatment, laboratory investigations, &c., the returns showing a total of 1378 attendances, or an average of 5·4 per patient. The payments to coöperating hospitals amounting to £1150 10*s.* are equivalent to a payment of £5 7*s.* 1*d.* a week for each in-patient and of 10*s.* for each out-patient, and include any provision which the hospitals may have made for a payment to general medical staff funds. Consultations in the patients' own homes were paid for by a fee of 3 guineas for each consultation. The amount allocated to nursing has been paid in full, but after paying for all the services rendered during the period, a balance of £406 remains in hand upon the other accounts, after all liabilities to members have been finally discharged.

Change of Name and Incorporation.

The committee feel that the year's experiment has fully justified their anticipations, and the statistical results encourage them to hope that in a system of provident coöperation lies the solution to the financial problem of the voluntary hospitals.

The report is signed by Sir Arthur Stanley, Lord Dawson of Penn, Mr. W. McAdam Eccles, Sir Alan G. Anderson, and Dr. J. F. Gordon Dill (hon. secretary), members of the Executive Committee.

On May 9th, 1923, the Association was registered under the Companies Acts, as a company not for profit, under the title of the British Provident Association for Hospital and Additional Services, the signatories to the memorandum and articles of association in addition to those named above being Lord Knutsford and Captain J. M. Gordon Dill.

RESEARCH IN TROPICAL DISEASE.

IV. THE WELLCOME BUREAU OF SCIENTIFIC RESEARCH.

THIS Bureau was founded towards the end of 1913 by Mr. Henry S. Wellcome, who, in 1902, had presented the laboratories bearing his name to the Sudan Government, and who has, in many directions, evinced his keen interest in tropical research. For the first few years of its existence the Bureau was housed at 10, Henrietta-street, Cavendish-square, but, subsequent to the war, removed to the premises it now occupies at 26, Endsleigh Gardens alongside the London School of Tropical Medicine, with which it has the privilege of coöperating in certain directions. From the start it has been under the direction of Dr. Andrew Balfour, formerly in the Education Department of the Sudan Government, director of the Wellcome Tropical Research Laboratories, Gordon Memorial College, Khartoum, and medical officer of health for that city.

The Bureau exists not only for purposes of research, more especially in connexion with tropical medicine and hygiene, but also with a view to supplying information gratis to medical men, sanitary administrators, and others interested in these subjects. From small beginnings it rapidly progressed, and though for a time its routine activities were curtailed by the war, the whole of its scientific staff being employed on military duties in one capacity or another, and for the most part abroad, work was resumed thereafter and has developed in various directions. There is now a deputy director, Lieut.-Colonel G. E. F. Stammers, R.A.M.C. (retd.), and departments of protozoology, pathology, bacteriology, helminthology, and entomology have been formed. In connexion with the last named, Mr. Wellcome has established a field laboratory at Wisley, Surrey, where work is carried out on mosquitoes and other insects of medical interest. An important feature of the Bureau is the large teaching and research museum of tropical medicine and hygiene arranged on graphic and somewhat novel lines; of which Dr. S. H. Daukes is the curator. This museum is freely open to all who may care to visit it, and arrangements are made whereby lecturers may bring their students and impart instruction to them in the museum itself. Evidence that these facilities are appreciated is given by the number of visitors and classes, the latter including many missionaries under training for the tropics.

Affiliated to the Bureau are the Wellcome Chemical Research Laboratories, which conduct researches in various departments of organic and inorganic chemistry and are specially concerned with plant analysis. Under Dr. T. A. Henry, late of the Imperial Institute, they collaborate with the Bureau in the investigation of native drugs, poisonous plants, spear, arrow, and fish poisons, and other matters intimately bound up with research in tropical medicine. The Bureau is also recognised by the Medical Research Council as an institution where its research workers may carry on investigations, and at the present moment two of its staff are engaged upon inquiries, dealing respectively with trypanosomiasis in British sheep and rat-bite fever.

Since its inception the Bureau has published over 100 papers dealing with many fields of tropical research, and has issued two volumes, one on tropical hygiene, the other on protozoology. As examples of the kind of work which has been undertaken, there may be cited the papers by Dr. C. M. Wenyon on malaria, intestinal protozoa, hæmatozoa, and Weil's disease; those by Dr. A. C. Stevenson on sleeping sickness, *Leptospira icterohæmorrhagiæ* in rats and the histopathology of typhus fever; those by Major H. C. Brown, I.M.S. (retd.), on remedies for dysentery; those by Dr. W. N. F. Woodland on porocephaliasis and on certain worms found in Nile fish; those by Mr. M. E. MacGregor on mosquitoes in England, and on myiasis; and those by Mr. G. C. Dudgeon on tropical fruit foods and certain parasites of rats. Joint work carried out with the staff of the chemical laboratories is evidenced by papers on the toxicity of emetine and on the reaction of the medium as affecting the toxicity of certain alkaloids towards protozoa, the latter being based on the combined researches of Dr. Henry and Major Brown. Apart from the war services rendered by the staff in several tropical and sub-tropical war areas, the Director-in-Chief carried out investigations in the West Indies and Central and South America prior to July, 1914, while of late years his services and those of Mr. MacGregor have been utilised by the Colonial Office in connexion with the sanitary regeneration of Mauritius.

In addition to research work in London the Bureau hopes to institute inquiries in the tropics and to link up the work at home with that abroad, where, it may be noted, museums modelled on that attached to the Bureau have been established in certain places, as, for example, Calcutta, Zanzibar, and Dar-es-Salaam.

BERLIN.

(From our own Correspondent.)

The Title of "Specialist."

The title of specialist has not hitherto been officially recognised; its assumption has been left to the discretion of a medical man and to the disciplinary power of his medical society, and the Government has declined to introduce a special examination or an official qualification in this connexion. The title has been abused—some medical men, after perhaps no more than a six weeks' post-graduate course, and sometimes without even that training, have placed it on their doorplates, thereby attracting patients to the detriment of their colleagues. The German Medical Association will deal with the matter at its next meeting; reports will be presented by a general practitioner and by a specialist. The reporters, Dr. Küstermann, of Munich, and Dr. Stuelp, of Mülheim, have published in the *Aerztevereins-Blatt*, the official journal of the Association, the proposals to be made to the meeting. They state that scientific and technical training superior to that of the average medical man is necessary for a specialist. Only the following branches of medical science are to be recognised as specialities: (1) surgery, (2) gynæcology and obstetrics, (3) orthopædics, (4) diseases of the eyes, (5) diseases of the ear, nose and throat, (6) diseases of the skin, venereal diseases, and diseases of the urogenital organs, (7) nervous and brain diseases, (8) radiography and heliotherapy, (9) diseases of the mouth and jaws, (10) diseases of the stomach and intestines and of metabolism, (11) internal diseases, (12) lung diseases, (13) diseases of children. The report states that it should be considered unprofessional to assume the title of specialist for more than one of those branches, except those closely connected—for example, surgery and orthopædics—but even this exception should be valid only for those already in practice; new specialists should choose one branch only. It should also be unprofessional to assume the double title of specialist and general practitioner, as is done in some parts of Germany. Specialist training should last for at least three years, and in relation to surgery, gynæcology, and internal medicine for four years. The intending specialist must have acted as an assistant in a university clinic, in a special department of a large hospital, in an out-patient department, and also as a private assistant to a specialist of good standing, the latter for a time not exceeding one-third of the entire training. A specialist desiring to practise should give notice to the local medical organisation, which will inquire as to whether he has fulfilled the conditions. Inquiry should be entrusted to a board consisting of specialists and general practitioners in equal number. If the board declines to recognise the specialist, the latter should have the right of appeal to the provincial medical chamber.[1] When, notwithstanding a definitive rejection of his claim, he insists on calling himself a specialist, he should be liable to prosecution before the court of honour of the chamber.[1] When treatment by a specialist is no longer necessary, the latter should send the patient back to a general practitioner, and should abstain from general practice himself. The report rejects the idea of legislative intervention in this important question, which, it states, should be left to medical discretion and settled by common agreement of specialists and general practitioners assembled in the next general meeting of the Medical Association.

Meeting of Socialist Doctors.

At a recent meeting of German and Austrian Socialist medical men in Berlin the chairman, Dr. Zadek, formerly a Berlin city councillor, pointed out that the number of socialists was smaller among the medical profession than in any other, as the sick-clubs, of which the great majority are under Socialist control, are somewhat hostile to the medical profession; medical socialists, however, were by their position fitted to settle disputes between these parties. Reports were read on the sick-club question in Germany and Austria; Dr. Epstein, of Munich, said that once the medical man became a State official, as required in the programme of the Socialist party, the struggle between individual medical men and the struggle of the profession against the clubs would cease. Prof. Grotjahn, a member of the Prussian Parliament, proposed that the clubs should appoint medical men for group work in rooms placed at their disposal on sick-club premises, and in hospitals, out-patient departments, and first-aid stations. Patients unwilling to consult the appointed medical men might apply to their club for higher sick-pay, and might then consult a private medical attendant. Dr. Weyl, a Berlin city councillor, advocated the appointment of a limited number of medical men; he believed that in Berlin 1500 medical men would suffice to secure an adequate attendance to club members, instead of the 3000 and more at present engaged in this work. He did not, however, say what would become of medical men excluded in this way. Dr. Kautsky, of Vienna, wished that medical officers elected by the clubs should again stand for election after two years, appointment for life being made dependent upon re-election. This might mean that before definitive appointment candidates would prescribe medicines lavishly and give certificates for sick-pay free in order to obtain votes. It was generally agreed that the nationalisation of the German medical profession as required by the programme of the Socialist party was impossible under the present financial conditions.

Control of New Drugs.

The German Association for Internal Medicine, together with the Association of Sick Clubs, have made arrangements for examination of new drugs produced by chemical manufacturers. A commission has been set up under the chairmanship of Prof. Klemperer to examine the efficacy and cost of new drugs; the commission may base their opinion on pharmaceutical and clinical testimonials produced by the manufacturer provided the certificates shown derive from trustworthy sources. Otherwise the remedy will be sent for pharmacological examination to a university or hospital. The drugs recommended by the commission after examination will be registered and the register published regularly, special mention being made of drugs suitably priced for use in sick-club practice. The clubs have provided the commission with adequate funds, hoping in this way to exclude certain new drugs which do not differ much from older remedies except by their sounding names and higher prices.

Conditions in the Rhenish Spas.

Since the beginning of the Allied occupation the Rhenish spas and health resorts have been in great distress. The majority of German patients decline to go there for sentimental reasons and also because the cost of living is several times more expensive in occupied districts than in the rest of Germany. Medical men practising at the Rhenish spas have appealed to their professional brethren in unoccupied Germany to send more patients; they assert that as the severe measures put into force by the occupying forces affect inhabitants only, the outside patient has nothing to fear and may take his cure as he desires. Many of the spas are of international renown, such as Wiesbaden, Ems, Kreuznach and Neuenahr; Homburg, so well known to English visitors, is not occupied but is seriously affected, being situated only a few hundred yards from the border of the occupied district. These spas were always chiefly, and are now nearly exclusively, frequented by foreigners, but Wiesbaden has now only a third of its pre-war numbers of patients, and Ems only a quarter. The great bathing establishments and kursaals of those spas are thus nearly empty. The loss to a city like Wiesbaden is estimated at milliards, and the municipal authorities have requested the German Government to allow the reopening of the gaming establishment closed by law in 1872. The appeal of the Rhenish medical men to their colleagues outside the Rhineland was, of course, made before the total blockade of the Ruhr and Rhine districts against Germans; but visitors belonging to the Allied nations may go there without special permission, and English visitors will certainly be as welcome as formerly.

ABERDEEN JOINT HOSPITALS SITE.—The Aberdeen town council has offered to dispose of the Burnside and Forresterhill estates to the parties of the proposed joint hospital accommodation scheme at a price of £35,000, the respective proportions of the price and ground being allocated as follows: Corporation (Public Health Dept.), 41 acres, at a cost of £13,335; Royal Infirmary, 36 acres, at a cost of £11,110; Sick Children's Hospital, 17¾ acres, at a cost of £5555; University, 10¾ acres, at a cost of £5000.

BURY INFIRMARY EXTENSION.—Lord Derby, at Bury, on July 14th, laid the foundation-stone of a war memorial, which will be an addition to the Bury Infirmary, and will be used as a children's hospital. The estimated cost, including endowment, is £12,500, of which £10,000 have already been subscribed. On the morning of the opening ceremony an anonymous donor sent bank notes for £1000.

Obituary.

DONALD MURRAY, M.B., C.M. GLASG., D.P.H.

Dr. Donald Murray, sometime Member of Parliament for the Western Isles, died in a London nursing home on July 6th at the age of 60. He was born at Stornoway, in the Isle of Lewis, on Oct. 21st, 1862, and received his medical education at the Universities of Glasgow and Aberdeen, graduating M.B., C.M. from the former in 1890. Taking up general practice first at Brora, in Sutherland, and then in his native burgh, he afterwards, in 1910, obtained the diploma in public health at the University of Aberdeen, and became medical officer of health for Stornoway and the Lewis district, as well as school medical officer for Lewis and the western portion of Ross-shire. He was soon elected to the chairmanship of the school board and a justice of the peace for Ross and Cromarty. Always a keen debater, he presided over the Glasgow Medico-Chirurgical Society when still almost a student, and he became president of the Glasgow University Liberal Club. In 1918 he was returned as Independent Liberal member of Parliament for the Western Isles Division of Inverness and Ross and Cromarty, but was defeated at the last general election by the National Liberal candidate.

Captain Walter Elliot writes: "As secretary of the Medical Committee of the House of Commons I saw a very great deal of Donald Murray during the four years 1918–22, and we soon became fast friends. I think it was impossible for anyone to know Murray without conceiving for him the warmest friendship and admiration. His sincerity, his devotion to the interests of the community which he represented, his gaiety, and, above all, his tremendous humanity, were qualities rarely combined in one man. In political matters he gained the respect of his opponents both by his knowledge and his really extraordinary power of hard work, and as a man it was, I think, the verdict of the House as a whole that he was the only medical member of the House of Commons of any party whom any of us, myself included, would really have wished to see at his bedside in time of sickness. This is perhaps the ultimate test of a man, certainly of a physician, and judged by it the name of Donald Murray stands high indeed."

ETTIE SAYER, M.B., B.S. LOND.,

CONSULTING PHYSICIAN TO THE SOCIETY FOR THE WELFARE OF THE FEEBLEMINDED.

Miss Ettie Sayer died on July 7th after a long illness at the age of 48. She was the daughter of William Sayer, of Bacton, Norfolk, and received her early education at Rossell School, Paignton, Devon, afterwards entering University College and the London School of Medicine for Women, where she was Chesterfield medallist. Graduating M.B., B.S. Lond. in 1889, she became house surgeon to the Tunbridge Wells Eye and Ear Hospital and then registrar to the St. John's Hospital for Skin Diseases, before accepting the appointment of physician to the Cowley Mission to Mahommedan and Kaffir women. In 1901 Miss Sayer was made plague medical officer to the Cape Government, and in this capacity she visited the concentration camps during the Boer war and later the lepers in Robben Island. After her return to England Miss Sayer was assistant medical officer (1902–07) to the Education Department of the London County Council and acted as lecturer on first-aid to that body and to the Church Army nurses. Her interests were many-sided: a Fellow of the Royal Society of Medicine and of the American Electro-Therapeutical Society, she was also a member of the council of the Psycho-Medical Society and of the Eugenics Society, and was the author of articles on the effects of electric currents on blood pressure, on the causes and treatment of inebriety, the deterioration of vision during school life, and on morally defective children, and she wrote a text-book for nurses on medical electricity and light. She was well known as an uncompromising supporter of women's suffrage and of other movements for the benefit of women and children. Miss Sayer's death will be mourned by a wide circle who recognised her pertinacity of aim and honesty of purpose.

Public Health Services.

WILLESDEN MUNICIPAL HEALTH SERVICE.

THE dispute[1] between the Willesden Urban District Council and the Willesden Branch of the British Medical Association has come to an end, the approval of the Ministry of Health having been received for the Council's maternity and child welfare scheme, by which children under school age requiring treatment will be dealt with in the same way as school-children. The scheme is as follows:—

Medical Examination and Advice.—Expectant mothers, nursing mothers, and children under five years may attend the municipal clinics for medical examination and advice, except mothers and children known to be under the care of a private medical practitioner. Mothers known to be under such care may, however, attend lectures or other educational meetings at the clinics.

Clinic Treatment.—(1) Expectant and nursing mothers and children under five years found to be suffering from nits or vermin may be treated at the clinics. Expectant and nursing mothers found to be suffering from minor ailments to the limited extent indicated in Memoranda M. and C.W. 14 and M. and C.W. 4 may be treated at the clinics strictly in accord with the provisions of these memoranda. (2) Expectant and nursing mothers found to be suffering from definite disease or deformity, or conditions other than minor ailments, shall be referred to a private medical practitioner. Children under five years found on examination to be suffering from defects requiring attention, other than nits or vermin, shall be referred to a private medical practitioner. (3) Children under five years found to be suffering from minor ailments, defective eyesight, enlarged tonsils and adenoids, or ringworm (for X rays), and in respect of whom a postcard has not been received from a private medical practitioner intimating that he has undertaken the treatment of the case, and who for good and necessitous cause shown cannot obtain treatment from a private medical practitioner or general hospital, may be treated at the clinics.

Home Confinements.—In cases where the economic circumstances of the family do not exceed the minimum scale figures, midwives, maternity nurses, and home helps are provided for confinements at home, and home helps are provided in connexion with hospital confinements or illness in the expectant mother.

The scheme is practically what the Willesden Division of the B.M.A. have asked for, and is now under the supervision of the chairman of the Public Health Committee and Hospital Subcommittee (Dr. G. W. R. Skene) and the chairman of the Children's Care Committee (Dr. W. Lock), both of whom are also members of the Divisional Executive Committee. These two medical men are largely responsible for the carrying through of the scheme in face of considerable difficulty.

MENTAL HOSPITALS SERVICE.

FOUR COUNTY AND BOROUGH HOSPITALS.

THE annual reports of four county and borough mental hospitals[2] recently published have many features in common, and deal with several matters of medical and public interest. It is, perhaps, not out of place to comment on the very brief and formal style which characterises them. It is frequently difficult to gain from them any clear picture of the work which it is their purpose to record. This must always appear as a missed opportunity of enlightening the public, and a few paragraphs which do no more than retail the main statistics in another form, and record minor structural changes and formal acknowledgments, can hardly be said to do justice to the vast amount of patient and careful work performed by the staff of such institutions.

Much of the important information in these publications is to be found in the reports of the Commissioners, who may express gratification at notably successful features of the hospital, or indicate directions in which some change is desirable. In three of these reports (the exception being West Humberstone) such recommendations are comparatively numerous, and are of a similar nature in each. The patients' diet (which usually costs about 5s. per head per week) is accused of monotony: a breakfast of bread and margarine and tea is the meal to which this comment is chiefly directed. In one case the women received this diet, whereas the men were given porridge and milk. The clothing, particularly of the women, requires improvement; it is pointed out that if patients had more reason to take some pride in their appearance, the effect, both on the clothing itself and on the wearers' well-being, would be far from negligible. In one case it appeared necessary that more tooth-brushes should be provided, and that care should be taken to mark and preserve them for individual patients. Another matter upon which comment is made is the degree of patients' freedom. The doors into the airing-grounds should be left open for longer daily periods; windows so constructed that to open them widely is impossible give an unnecessary sense of confinement; more patients should be allowed liberty in the grounds and outside them; more should be allowed out on trial, and such patients should receive a money allowance to enable them, if possible, to make a new start in life. Other suggestions are that letter-boxes should be provided in each ward, the key being kept by a medical officer, and that more cards and other games should be available. In two of the hospitals no dentist attended regularly. At Worcester, the post of third assistant medical officer has been vacant for some months, and a Commissioner expresses surprise that no married quarters are available for any medical officer other than the superintendent. The committee are considering the desirability of providing such married quarters, of improving the water-supply (to which two deaths from paratyphoid are attributed), and of reconstructing part of the male side to permit of proper accommodation for recent and recoverable cases. At West Humberstone a dentist has been appointed and an X ray plant installed. An additional medical officer is to be appointed whose time will be devoted chiefly to pathological work. Further innovations are the keeping of case-sheets in the wards themselves, and the provision of rooms where interviews or psychotherapy can be undertaken in private.

These improvements and defects are worthy of comment, in that many of them are engaging the attention of mental hospital committees throughout the country. It is foolish to deny that such defects are common to a large proportion of county and borough mental hospitals, and on the other hand, it is worthy of record that some are being remedied. The difficulty which in every case stands in the way of improvement is money. Organisation and treatment are as nearly perfect as the resources of the institutions permit, but the amenities which characterise life in a hospital for private patients, and play no small part in promoting recovery, can only be provided if the local authorities consent to an increase in expenditure. On these lay bodies rests the responsibility of "asylum reform."

SCHOOL MEDICAL SERVICE.

Dewsbury.

THE school medical officer makes some interesting observations in connexion with the nutritional condition of the school population in Dewsbury for 1922 as compared with 1921. In 1921 the percentage of children with so-called malnutrition was practically the same for all ages. In 1922 a progressive deterioration is shown as both boys and girls advance in years.

---

[1] THE LANCET, 1921, ii., 1124; 1922, i., 150.

[2] The annual reports of the County and City of Worcester Mental Hospital, Powick; Cumberland and Westmorland Mental Hospital; City of Leicester Mental Hospital, West Humberstone; and Borough Mental Hospital, Middlesbrough.

> "The comparatively big difference in the 5-year old group as compared with the 8-year old group is hard to account for, but evidently during the three intervening years some cause or causes have been in operation affecting adversely the normal rate of development. Perhaps the zymotic diseases play the important rôle, as they are more liable to attack children between 5 and 10 years of age. Again, the 8-year old group was born in 1914, and the children were therefore affected by the food shortage of 1917–18."

Obviously the latter explanation ought to have affected the figures for 1921 as well as those for 1922. All school doctors and teachers have noticed the difference in the groups of children entering school each year; one year there will be a fine, healthy crop of children and the next year a poor one. Dr. C. J. Thomas in 1905 investigated very thoroughly groups of children born in different years who had attained the ages of 8 to 13. He found that children born in a year with a high child mortality rate were poorer physically and mentally than children born in a year with a low rate. The high mortality rate may have been produced by various causes—a hot, dry, dusty summer with epidemic diarrhœa, or a year when infective disease was rife, carrying off a large number of children and weakening others. The younger the child the greater the effect of any debilitating influence on growth. Out of a total of 2504 children inspected in the routine group, 563 required actual treatment; 309 were found suffering from malnutrition, 53 from skin disease, 207 had enlarged cervical glands (non-tuberculous). Of 1434 inspected by the dentist, 1171 were referred for treatment, and 643 actually treated. Dr. O. M. Holden reports that the accommodation at the baths is inadequate for the needs of the school-children and the inhabitants of the town, and urges an increase of washing facilities.

Warwickshire.

The school population here is about 37,500, distributed between 314 schools, compared with 319 in 1921, the reduction being due to the amalgamation of departments in several schools with a view to economy of teaching staff. During the year 12,053 routine medical examinations have been made, and of these 16 per cent. were referred for treatment. At the school nurses' examinations of 15,660 children 10·3 per cent. were found with unclean heads, a slight improvement on the 14·8 per cent. found in the previous year. Dr. A. Hamilton Wood finds it very disheartening to have to record that after 14 years of medical inspection so little attention is paid by parents and teachers to the uncleanly condition of children's heads, and says that too often the question is regarded by the head teacher as a matter for the school doctor and nurse, and one in which the teacher is not concerned. He finds in those schools where the teachers take an active interest in such matters that a high standard of personal cleanliness is obtained. Ringworm incidence, although about a hundred cases less than last year, is high, amounting altogether to 435 cases; 50 of these were given X ray treatment. Following-up is undertaken entirely by whole-time health visitors in their capacity as school nurses, to which they devote one-third of their time. This scheme appears to be working well. During the year they kept under observation 10,108 cases, treatment being obtained for 8948 of these. There were 223 fewer cases of enlarged tonsils and adenoids recommended for treatment during 1922 compared with 1921, and only £18 was spent in connexion with the provision of free meals for necessitous children living in the outskirts of the city of Coventry, as against £160 for the previous year. The reason for this is not clearly set out. This report is presented in foolscap form, and is somewhat unwieldy and difficult to handle.

EPSOM COLLEGE.—Founder's Day celebrations will be held on July 30th, when Lord Muir Mackenzie will distribute the prizes.

Correspondence.

"Audi alteram partem."

THE BEST DENTAL ANÆSTHETIC FOR CHILDREN.

To the Editor of THE LANCET.

SIR,—Mr. S. F. Rose's article in your issue of June 23rd, and Dr. H. Hilliard's letter in that of July 7th, prompt me to put forward the claims of nasal nitrous oxide and oxygen as a satisfactory anæsthetic in dental operations on children. Mr. Rose says that children take gas badly; Dr. Hilliard suggests that this is because they will not stand deprivation of oxygen. Why, then, not gas and oxygen?

The disadvantages of ethyl chloride as a dental anæsthetic in children, in comparison with nasal gas and oxygen, are, to my mind, that firstly, it is probably less safe; secondly, recovery is slower and after-results more likely (important points for a busy dentist, as well as for the patient); thirdly, it is less pleasant to take (with the result that the child is more likely to dislike any subsequent administration), and fourthly, the available anæsthesia is shorter. Mr. Rose advises immediate second or third doses to complete a difficult operation. The mental anguish and fear attending such a procedure in some children is, I am sure, very great, and I consider it unjustifiable unless it is absolutely unavoidable.

Undoubtedly children are more difficult subjects for nasal gas-oxygen than are adults, but nevertheless satisfactory results can be obtained. Children almost invariably induce quietly and easily without any contact between nose-piece and face being necessary, with the result that they usually do not mind the anæsthetic. Continued administration is the more difficult part, with a child's active reflexes, but, nevertheless, with experience, more satisfactory results than with ethyl chloride, as regards length of operation time and quick recovery, can almost always be obtained.

In unruly children, in whom cavity preparation is difficult, nasal gas-oxygen is a method offering a chance of completing work otherwise almost impossible. I can recall the case of a boy of 6 or 7, otherwise almost unapproachable dentally, in which three cavities were prepared and temporarily filled during an anæsthesia of about 20 minutes.

I never give ethyl chloride for dental work unless there be most unusual circumstances demanding it. I have only given it, in dentistry, once in the last three years, and then because the child was so spoilt and unruly that it was the only method in which he could not smash the apparatus. Such cases are rare.

I am, Sir, yours faithfully,

Harley-street, W., July 10th, 1923. STEPHEN COFFIN.

L'AFFAIRE SPAHLINGER.

To the Editor of THE LANCET.

SIR,—In writing to give you my personal opinion of the Spahlinger treatment, I cannot do better than quote the following case of my own:—

A man, aged 32, suffering from tuberculosis of the left kidney, the right kidney being sound (diagnosis by cystoscopy and ureteral catheterisation), and from non-fistulous right tuberculous epididymitis, had left nephrectomy performed on Oct. 30th, 1919, with no untoward after-effect. In May, 1920, began almost constant hæmaturia, with exaggeration of vesical symptoms. In the following July occurred left epididymitis, which opened rapidly by means of two fistulas. The right epididymitis increased, but did not become fistulous. I saw the patient again in August, when hæmaturia was still almost continuous. Having ascertained by means of the cystoscope that the latter was due to the remaining kidney, I decided that the tuberculosis must be localised on that side, and determined, in view of the gravity of the case, to try the Spahlinger treatment. From August 20th to Oct. 27th I gave several injections of serum (B.M.). There was a violent febrile reaction (max. 39·6°–40·2° C.), and painful reactions took place in the left testicle and in the operation wound, with increased hæmaturia, at the beginning of September. The hæmaturia ceased on Sept. 6th, and up to the present (July, 1923) has not reappeared. During the injections there was much suppuration from the fistulas in the left epididymis.

From the date of the last injection, Oct. 27th, the patient's general condition gradually improved. He was a mechanic, and in the spring of 1920 his bad health had forced him to give up his work; he is now working full time, with good general health, good colour, &c. His urine is opalescent with phosphates and muco-purulent débris; micturition is painless and takes place once nightly. The right epididymis is painless, rounded in shape, and the size of a nut; the nodular left epididymis is adherent to the skin of the scrotum at the level of the two dried-up fistulas.

It seems to me impossible to deny the good effect of the treatment in this case. The least that can be claimed is a distinct modification of the clinical course, and, of course, of the tuberculous lesion in the second kidney, which at the time of the nephrectomy was healthy. The patient was doubtless unfit to resist the second attack of the disease, and his general condition was rapidly growing worse. Since treatment, and in spite of resuming work, the evolution of the lesions appears arrested in both kidney and epididymis, and his general condition is that of a healthy man.

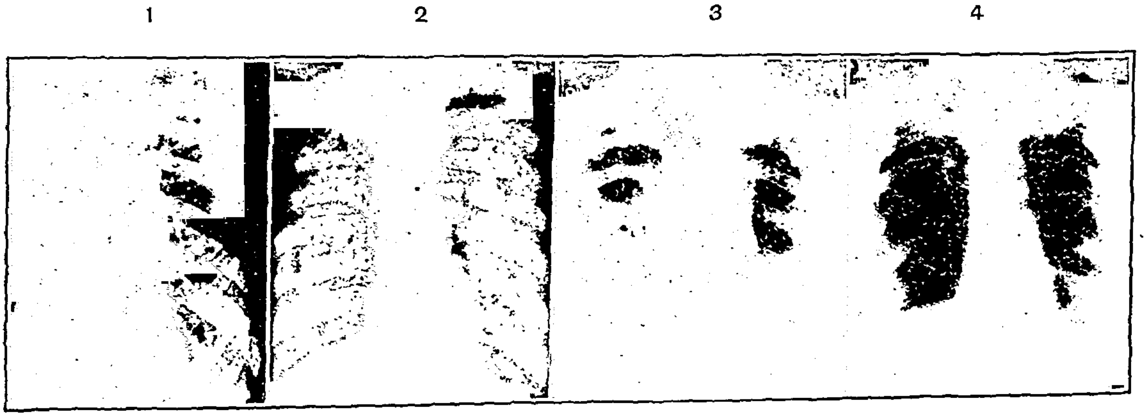
I am, Sir, yours faithfully,

Charles Perrier,
Privat-docent, Chirurgien-Adjoint à l'Hôpital Cantonal, Geneva.

July 3rd, 1923.

To the Editor of The Lancet.

Sir,—I have had the privilege for the last eight years of having treated a number of cases with Mr. Spahlinger's partial sera and with his vaccines. Although I have never used the "complete" serum, I rapidly came to the conclusion that Spahlinger's partial sera produce most favourable results in the treatment of acute or severe tuberculosis, results which no other hitherto known treatment could give. A series of cases, mostly in an advanced and rapidly progressing stage of the disease when they came under my care, were treated with these antitoxins and are alive to-day, and engaged in their normal work. I quote four typical interesting cases :—



Radiograms: 1. Case 3 when marked improvement had taken place. 2. Case 3 after recovery. 3. *Case 4 when partial serum treatment was commenced.* 4. Case 4. Radiogram taken one year after.

Case 1.—F. L., male, aged 25. Patient had coxalgia at 9 years of age. Treated by extension and sea-baths, as a result of which condition improved. There remained, however, a permanent focus in the track of the fistulous opening. Up to the moment when Spahlinger's treatment was commenced, the patient had continual relapses, which necessitated frequent medical and surgical intervention. Three operations took place; the last one, which was of an urgent nature, was performed in 1915. It necessitated making an incision of about 8 inches and inserting four drainage-tubes. In order to dry up the suppurating lesion and to avoid abscess formation, which occurred after each preceding operation, patient was in 1915 treated with Spahlinger's vaccine. Cicatrisation of the wound rapidly took place and the suppuration disappeared. Treatment was continued for eight months with one interruption of a few weeks.

Examination in June, 1923, shows complete arrest of the *disease. It is interesting to note that before Spahlinger's* treatment was commenced, abscesses formed periodically, necessitating continual care and preventing patient effecting a complete recovery. Since receiving the course of vaccine in 1915, patient has had no relapse whatever and for seven years has now been able to lead a normal life.

Case 2.—G. V., male, aged 30. Four years ago patient had a severe hæmorrhage. Early in 1913, while working at Algiers, he suffered from violent cough, repeated attacks of hæmoptysis, weakness, breathlessness. Pulmonary tuberculosis was diagnosed. He received hospital treatment at Algiers with ensuing improvement. From March until August, 1914, condition became slowly worse. Sent back to France. When patient came under my care in July, 1915, his chest examination showed extensive bilateral fibro-caseous infiltration with softening well marked at apices. His cough was troublesome, the daily expectoration amounted to 8 oz., and T.B. were present in large numbers. Slight rise of evening temperature. Frequent hæmorrhages. Loss of weight 8 lb. *during the last six months* (normal weight unknown). Night sweats. Dyspnœa very troublesome. No appetite. Anæmia. Fainted on slightest exertion.

After a 12 months' course of Spahlinger's *serum* and vaccine the signs in chest had completely dried up, and general condition had much improved, when patient had a sudden attack of hemiplegia, with a positive Wassermann. He died the week following from a syphilitic gummata in the brain. His post-mortem revealed extensive scar tissue throughout both lungs.

Case 3.—H. N., male, aged 23. Patient contracted bronchitis in 1913. Cough ever since. In July, 1914, had hæmorrhage. In November, 1914, sputum examination showed T.B.+ and pulmonary tuberculosis was diagnosed. He had a course of tuberculine injections at the beginning of 1915. Hæmorrhages in March and April. When patient commenced Spahlinger's serum treatment in May his chest examination showed infiltration of right upper and middle lobes and also at left apex. He complained of cough, profuse *expectoration, often* blood-stained, T.B.+, loss of weight, night sweats, temperature 101·1°F., pulse 110, dyspnœa, indigestion, diarrhœa, vomiting.

By July marked improvement had taken place, and treatment was stopped temporarily for want of antitoxins. In August new increase of activity, severe and prolonged attack of hæmorrhages. In November condition had become very critical, and a fatal termination appeared imminent. Temperature, 101·2–102·4°; pulse, 120; cough extremely troublesome; expectoration purulent, amounting to 9 oz. daily, numerous T.B. present, extreme emaciation, profuse night sweats, much dyspnœa, diarrhœa. Condition of collapse. Examination showed massive disease of the whole of right lung and scattered infiltration on left side. Serum treatment was resumed and antitoxins given in large doses. By end of December a slight but marked improvement had taken place. Patient could eat a little food and hæmorrhages had stopped, but he was still too ill to sit up in bed for thorough auscultation. End of February, 1916, he was allowed to get up. Temperature was then normal. Condition improved rapidly. In December, 1916, the disease was completely arrested, nevertheless serum treatment was continued until end of 1917. Examination in 1923 shows that there is no trace of active tuberculosis in the chest. Patient has no cough and no sputum. His weight is normal (41 lb. increase since December, 1915). There is still some dyspnœa present. He has been at work as a journeyman tailor since 1917 up to the present day.

CASE 4.—S. Y., woman, aged 42. Tuberculosis in family history. Three sisters, one brother, and husband died of pulmonary tuberculosis, and her only child died of tuberculous meningitis. Patient contracted pleurisy and pneumonia in 1916. Went to sanatorium. In November, 1917, T.B. were found in sputum. Hæmorrhages in June, 1919. Returned to sanatorium. In January, 1920, went to Leysin and in October to Davos, where she was diagnosed as a cavernous form with marked process of caseation; she remained there until March, 1921, gradually getting worse. When patient came under my care in April, 1921, chest examination showed considerable caseous infiltration at R. upper lobe and infiltration at lower lobe. Rapidly spreading disease at L. side with caseous infiltration of two-thirds of L. upper lobe and also infiltration at base of lower lobe. Active softening at both apices. Her cough was troublesome. The yellowish, purulent expectoration amounted to 5–6 oz. daily, with numerous T.B. present in it. Pulse 90–110. Loss of weight 1 st. 5 lb. Hæmoptysis. Much dyspnœa.

After two years of Spahlinger's partial serum treatment the disease is now (June, 1923) completely arrested. Temperature, pulse, and weight normal. There is a little cough and phlegm in the morning, but since the beginning of 1923 the sputum examination has always remained negative. Patient is very well and leads a normal life. She is still receiving partial serum injections once a week.

Some of the cases are still receiving once or twice a week an injection of partial serum, while awaiting a course of active immunisation which, unfortunately, is unavailable at present. On the other hand, the 11 patients I treated with Spahlinger's vaccine in 1915–16 have made a lasting recovery and have had no treatment whatever since their discharge. Two of these patients were suffering from tuberculosis of the bones, duly confirmed by bacteriological tests, and nine were pulmonary cases, with T.B. present in each sputum examination. Unfortunately three of them died subsequently from diseases other than tuberculosis. The remaining cases have been in perfect health for the last seven years. They are able to lead a normal life, engaged in active work, and on no occasion have they shown any signs of relapse.

I am, Sir, yours faithfully,

Geneva, July 3rd, 1923. DR. E. TRECHSEL.

MENTAL HOSPITALS SERVICE.

To the Editor of THE LANCET.

SIR,—In your review of various mental hospital reports under the above title in THE LANCET of July 14th reference is made to The Retreat and to Barnwood House, Gloucester, under the heading "Two Private Mental Hospitals." The two hospitals mentioned are in reality "registered hospitals"—that is to say, establishments managed by a voluntary committee, none of whom have any pecuniary interest in it. In this respect they are thus precisely on the same footing as the Scottish Royal Asylums. As the phrase "Private Mental Hospital" properly refers, not merely to institutions for private patients, but to those which are managed for the profit of some person or company, I think it worth while to draw your attention to the inaccuracy.

I am, Sir, yours faithfully,

HENRY YELLOWLEES.

Laurel Beeches, York, July 17th, 1923.

*** The heading was not intended to convey more than that the two hospitals mentioned were for private patients.—ED. L.

THE LINGUAL TONSIL IN RELATION TO THE SINGING VOICE.

To the Editor of THE LANCET.

SIR,—In the condensed report of the discussion on Mr. Seymour Jones's interesting paper on the Lingual Tonsil in THE LANCET of June 23rd, p. 1265, some speakers suggested that too much importance might be attributed to it. There is, however, one of its aspects—namely, the effect of its enlargement on the singing voice—which I think is of considerable importance. Briefly, this condition interferes with the elevation of the epiglottis, which accompanies, and is probably essential to, the clear production of the higher notes. Removal of sufficient of the redundant portion to relieve the pressure on the epiglottis has been followed by increased comfort in singing, and by the gain or recovery of several notes. The point receives consideration in my lecture[1] on "Some Disturbances of the Singing Voice."

I am, Sir, yours faithfully,

London, July 14th, 1923. JAMES DUNDAS-GRANT.

THE RÔLE OF THE TOOTH-BRUSH.

To the Editor of THE LANCET.

SIR,—The letter of Sir John O'Conor, published in THE LANCET of June 2nd, has been read with interest, but also with great surprise. It is certainly most astonishing to find any one willing to make such sweeping statements that the daily use of a bristle tooth-brush is harmful, and at the same time offer nothing to corroborate his views. The fact that the gentleman states that dental caries and pyorrhœa come from the use of the tooth-brush shows the lack of careful investigation on his part. The correct brushing of the teeth and gums not only removes food debris, but strengthens and hardens the gums and stimulates the blood-supply to the teeth.

Had Sir John O'Conor stated that the ailments he enumerates are largely due to the use of foods which do not need mastication he would have more closely approached the truth. Hard and dry foods requiring mastication and insalivation will give the necessary exercise to dental organs and bring into proper play those functions which will keep the teeth and adjacent tissues in normal, healthy condition. Cooked foods, tinned foods, sloppy foods, bread made of wheat, from which all the most important elements have been removed, oatmeal drowned in milk and smothered with sugar, jams, sweets, mashed potatoes, and juicy tender flesh which dissolves and does not need much effort to masticate, these are far more productive of pyorrhœa and dental caries, gastric pollution, and appendicitis than are all the tooth-brushes ever made since time began. In the conditions and environments that men live to-day, the tooth-brush is a necessity for the maintenance of mouth hygiene. In the United States we are collecting a vast amount of valuable data showing the importance and value of using the tooth-brush three and four times a day.

The oral hygiene movement has taken a firm hold in our country and there are signs that the people of England are taking up this subject with zeal and thoroughness. In the city of Bridgeport, where the daily use of the tooth-brush has been taught in every public school for the past five years, and where every school child has a tooth-brush, a large reduction of children's illnesses has already been recorded. A large reduction of dental caries and a 50 per cent. reduction in backward children has also been secured. During the past eight years over 50,000 cleansing operations have been given to the employees of the Metropolitan-Life Insurance Company. Instructions are also given for the proper use of the tooth-brush. In all these years and for all these thousands of persons there has not been one case of pyorrhœa, dental caries, gastric pollution, appendicitis, or organism decomposition that has been traced to the daily use of the tooth-brush. Nay, further, it can be shown that the improvement in general health has been so marked, that whereas, during the first four years it was optional with the employees to have their teeth cleansed, now it is a rule of the company that every one of its seven thousand employees must have two cleansings each year. Dr. Geis and Dr. Kleiger of Columbia University found that one milligramme of tooth scrapings in an uncared for mouth contained from five to eight hundred million bacteria by count and weight, whereas, in one milligramme of tooth scrapings in a fairly clean mouth there were approximately only five million. It can be safely stated that the bacteria found in a clean mouth are to all intent and purpose practically harmless, whereas those that are found in a dirty mouth become virulent and dangerous. Another factor is the question of the health of the soft tissues of the mouth. When the soft tissues of the mouth are in a normal condition, they are practically impervious to bacterial life, but when the gums become inflamed, they then become open gateways for the entrance of disease germs into the circulatory system of the body.

---

[1] Clinical Journal, 1913, xlii., 504–5.

Nothing will bring about more quickly an inflamed condition of the soft tissues surrounding the teeth than the lack of proper and sufficient mastication upon hard foods and the presence of decaying particles left from mushy meals. The formation of calcium deposits also causes inflammation of the gums. By the proper use of the bristle tooth-brush and tooth-powder and rinsing the mouth with lime-water after cleansing will do more for the hardening and strengthening of the gums, the prevention of pyorrhœa, and dental caries than any other known remedy. I have yet to see a patient who uses a badger-hair tooth-brush who did not have a mouth reeking with food debris a week old, and with inflamed gums and pus discharge. Until the food habits of the entire civilised world are changed, bristle tooth-brushes are a necessity for the maintenance of mouth hygiene.

I am, Sir, yours faithfully,
THADDEUS P. HYATT, D.D.S., F.A.C.D.

New York City, July 5th, 1923.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Rear-Admiral J. Shand will be succeeded by Surg. Rear-Admiral J. F. Hall in charge of the Royal Hospital, Malta.

Surg. Vice-Admiral Sir R. Hill, Director-General of the Medical Department of the Navy, to be Honorary Surgeon to His Majesty, vice Inspector-General of Hospitals and Fleets W. H. Lloyd, deceased.

Surg. Rear-Admiral G. A. Dreaper is placed on the Retd. List.

Surg.-Capt. A. Gaskell to be Surgeon Rear-Admiral.

D. H. Kernohan is entered as Surg. Lieut. for short service.

ROYAL ARMY MEDICAL CORPS.

Temp. Hon. Lt.-Col. T. E. K. Stansfield relinquishes his commn. and retains the hon. rank of Lt.-Col.

Lt.-Col. A. F. Carlyon, late R.A.M.C., half pay, retires on account of ill-health contracted on active service.

The undermentioned retire on ret. pay: Lt.-Col. G. H. Goddard on account of ill-health; Maj. R. J. C. Thompson on account of ill-health contracted on active service (and is granted the rank of Lt.-Col).

Capt. R. W. Galloway relinquishes the temp. rank of Maj.

Temp. Capt. F. J. P. Daly relinquishes his commn. and retains the rank of Capt.

ARMY DENTAL CORPS.

Lt. N. H. Medhurst to be Capt.

TERRITORIAL ARMY.

Maj. J. V. Bates (late R.A.M.C.) to be Capt., and relinquishes the rank of Maj.

Lt. J. W. Macfarlane to be Capt.

Lts. J. R. Oddie (from 5th Bn. West Yorkshire Regt.) and A. Badenoch (late R.G.A., T.F.) to be Lts.

TERRITORIAL ARMY RESERVE.

Lt.-Col. E. J. D. Taylor (from 5th Southern General Hospital) to be Lt.-Col.

Capt. P. E. H. Adams (from 3rd Southern General Hospital) to be Capt.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. Ainsworth to be Colonel.

The King has approved the retirement of Lt.-Col. S. H. Burnett.

SIXTH CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY.

THE International Society of Surgery is holding this week, July 16th to 20th, its Sixth Triennial Congress, the first to be held in this country, at the house of the Royal Society of Medicine, at 1, Wimpole-street, under the presidency of Sir William Macewen, F.R.S.

MONDAY, JULY 16TH.

On Monday members' obtained detailed programmes for the week; only a business meeting of the international committee took place. On that evening a conversazione was held at the University of London; members of the Society and ladies were received by Mr. H. J. Waring, Vice-Chancellor of the University, and Mrs. Waring, and had opportunities of renewing old acquaintances and making new ones. The band of H.M. Scots Guards played musical selections and light refreshments were provided.

TUESDAY, JULY 17TH.

INAUGURAL SESSION.

On Tuesday, at 11 A.M., the inaugural session was opened by H.R.H. the Prince of Wales. His Royal Highness was received by Sir Wm. Hale-White, President of the Royal Society of Medicine, and signed the roll as an Honorary Fellow. He was then welcomed by the President of the Congress and presented with the Society's medal in gold. The Prince referred to the international aspect of the gathering, now for the first time meeting in Great Britain in the house of a Society of which he was an honorary member, and welcomed the delegates and members from other countries. Modern surgery was, he pointed out, the outcome of international coöperation, since it owed its inception to the work of Pasteur and Lister. A special welcome was extended to Dr. W. W. Keen, of Philadelphia, the doyen of the Congress. Lord Curzon welcomed the delegates on behalf of the Foreign Office. Such meetings, he said, while they might produce fruitful rivalry between nations, were a valuable part of the machinery of international amity. He wished he could apply surgical methods to the ills of the body-politic with the same accuracy and prospects of success. Mr. Neville Chamberlain hoped the Congress would be attended with results fruitful to mankind. Already no more useful advance had been made in any branch of science than in surgery; much progress had been achieved in the late war, notably in plastic or reconstructive surgery. Illness resulted in economic loss, and anything that tended to cure disease or shorten it deserved the gratitude of all nations. Mr. J. E. H. Roberts, the British delegate, briefly welcomed foreign delegates, and thanked them for choosing London as the venue for the Congress. The following delegates were then presented to His Royal Highness: Dr. Bruce (Canada), Dr. Zacharicky (Czecho-Slovakia), Dr. Hansen (Denmark), Dr. Petridis (Egypt), Prof. Hartmann (France), Dr. Koch (Holland), Dr. Allessandri (Italy), Dr. Nicolaysen (Norway), Dr. de Zawadski (Poland), Dr. Kayser (Sweden), Dr. de Quervain (Switzerland), and Dr. MacArthur (United States). Prof. Willems, President of the International Committee, after thanking the Prince of Wales for his presence and gracious words, pointed out that this was the first occasion upon which the President was a subject of the country where the Congress was held. A list of the members whom the Society had lost since its last Congress was read.

Dr. L. Mayer, Secretary-General, cognisant of the Prince of Wales's knowledge of that language, spoke in French, and thanked the Prince and the Ministers for their presence at the inaugural session. He referred to the lamented death of Sir Charles Ryall, whose place as organising secretary had been taken with conspicuous success by Mr. Roberts, to whom, with Sir

D'Arcy Power, the thanks of the Congress were due for the splendid organisation. The President of the Society, Sir William Macewen, delivered an address in which he suggested that much could be learnt about human anatomy from a study of animals. The growth of a stag's antlers, for instance, provided a fascinating subject which might well provide an insight into the growth of bone. In three months the stag produced a complicated pair of antlers composed of solid bone covered by a vascular "velvet." Yet these bony excrescences grew from the frontal bone which was covered by pericranium, a membrane which, even according to the orthodox view of the osteogenetic function of periosteum, had only the most meagre bone-forming powers. In a few months more the antlers underwent a process of aseptic sclerosis and death, and were finally shed, this being contrary to Metchnikoff's theory that senility of tissues was the result of bacterial invasion. Histological examination of the antlers made it possible to recognise the osteoblasts by their form, and to trace them through all the stages of growth and shedding. Sir William Macewen was sceptical of the theory that mesoblastic cells had the property of converting themselves into any other form of mesoblastic cell, and stated his belief that bone-cells were invariably developed from bone-cells, and that certain bone-cells had inherited greater osteogenetic power than others. It was well that it should be so, for otherwise bony injuries would produce serious deformities; 40 years ago he had been able to prove that bone grew from bone, by reproducing a humerus from pieces of bone removed from other human subjects.

FIRST SCIENTIFIC SESSION.

The first scientific session, held on the afternoon of Tuesday, was devoted to the surgery of the endocrine glands.

Surgery of the Thymus in Early Life.

Dr. Victor Veau (Paris) said that enlargement of the thymus, which was responsible for many deaths in infancy, was amenable to surgery. Thymectomy was an easy operation, devoid of any serious risk and curative if the diagnosis were correct. But as there must always be a little doubt about the diagnosis and as a similar result could be obtained by one or two doses of X rays he preferred now to employ radiotherapy rather than surgery. The X rays were not altogether devoid of risk; should this risk prove to be serious he would revert to surgery.

The Splenic Syndromes.

Dr. W. J. Mayo said that the spleen was chiefly a mechanical filter, which removed degenerated red cells and toxic agents from the blood. It sent them on to the liver for further detoxication; it also developed lymphocytes. The function of the normal spleen was not important, but the diseased spleen was a serious menace to the constituents of the blood and to the liver. The spleen did not initiate the pathologic processes with which it was concerned, but acted as a secondary agent. The removal of the spleen in the splenomegalies and in certain blood conditions removed a pathologic agent. A spleen that was chronically enlarged and did not yield to reasonable medical treatment should be removed early, unless in the individual case there were contraindications to splenectomy.

Two hundred and ninety-five splenectomies had been performed at the Mayo Clinic, and all the deaths were classified as being due to the operation.

Splenomegalies due to Micro-organisms.

Cause.	No. of splenectomies.	Deaths.	Results.
Chronic syphilis	8	1	Good in 7 cases.
Tuberculosis	4	1	„ 3 „
Pyogenic organisms ..	11	4	„ 6 „
Splenic anæmia	82	9	„ majority.

Hæmolytic Icterus.—Forty-two splenectomies were performed for this condition, one died in hospital, and 40 recovered perfectly.

Pernicious Anæmia accounted for 57 splenectomies; there were three deaths in hospital, but no deaths amongst the last 40 patients prepared by blood transfusion, and the improvement in all was more prolonged than in that following blood transfusion alone; there were no cures, but the abnormal blood picture improved. He thought splenectomy in cases of pernicious anæmia was only justified in a limited number of carefully selected cases.

Polycythæmia Rubra Vera.—One splenectomy was performed for this condition. There was great improvement. The patient was able to work.

Hæmorrhagic Purpura (essential thrombohæmia).—One splenectomy was performed with good result.

Splenomyelogenous Leukæmia.—Twenty-nine splenectomies were done for this disease with only one death in hospital, and great temporary benefit in 28. The condition of the blood was improved, but was not normal. The other 59 miscellaneous cases were not discussed in this paper.

Some Points in the Surgery of the Suprarenals.

Drs. Ch. Willems (Liége) and N. Goormagtigh (Gand) said: In classifying suprarenal tumours, the morphological, functional, and embryonic distinction between the cortex and the medulla was most important. The "cortico-surrénalomes" were the most frequent, while the tumours of the medulla were most rare and belonged to two groups—those of nervous origin, and those of chromaffin origin.

The syndrome of Sargent-Bernard presented an acute form corresponding to the destruction of the glands, and a less serious form which probably corresponded to partial lesions. This was, however, controversial. The former had the appearance of an intoxication, while the latter form presented as principal symptoms hypotension and asthenia. The excision of one of the healthy suprarenals, with the idea of lessening the amount of suprarenal substance, had been performed, especially for epileptic fits. The results obtained were interesting, but the problem was far from solved. The removal of the suprarenal had also been performed in cases of hypertension, so as to reduce the suprarenal functions. Of the two ways which had been used for the extirpation of the healthy suprarenal, the transperitoneal one was not the handiest in spite of its appearance. The retroperitoneal way, according to the technique of the authors, was more advisable, being more accurate and giving the required view.

Pituitary Surgery.

Mr. Percy Sargent (London) said that considerable progress in pituitary surgery had been made since Victor Horsley's pioneer operations of more than 20 years ago, but there was still much to be learnt. Operation might be directed to (*a*) influencing the secretory output, (*b*) relieving local pressure symptoms, (*c*) relieving general intracranial pressure. Total removal of a pituitary tumour was impracticable, but partial removal might be of great benefit. In some cases a simple decompression operation was all that could be done, and might be very beneficial, even as regards vision. The causes of failure, in the speaker's opinion, were: (i.) errors of diagnosis leading to misdirected operations; (ii.) massive intracranial extension of the tumour, rendering the case unsuitable for any operation except a palliative decompression; (iii.) operative accident; (iv.) post-operative pneumonia; (v.) in trans-sphenoidal operations, septic infection.

The osteoplastic frontal approach was the procedure chosen in most cases; the trans-sphenoidal operation, although presenting certain advantages, was incapable of affording more than partial and transient relief. Advance in pituitary surgery must come about through improved diagnosis, wiser selection of cases, and earlier operations.

Surgery of the Thymus.

Dr. Lorthior (Brussels), after a brief reference to the possible function of the thymus gland, went on to discuss the indications for its removal, the chief of which was thymic asthma; there were other indications, such as laryngismus stridulus, respiratory embarrassment leading to debility and arrested mental development, intolerance of anæsthetics, &c., and their number was increasing. After removal of the thymus there was often a striking improvement in the general condition of the child, in its intelligence, vitality and rate of growth, resembling the effect of removal of adenoids. The operation was conducted as follows. After being anæsthetised (the reporter's preference was for chloroform, although other general anæsthetics, ether, nitrous oxide, &c., could be employed) the child was placed in Rose's position and a small incision about one inch in length was made vertically upwards from the suprasternal notch. The muscles having been separated, the thymus in its capsule was seized with forceps when it appeared from behind the sternum during expiration; the capsule was opened and the gland substance proper seized with forceps. From this moment the hold upon the gland by forceps must not be released until the gland had been removed by gentle and patient traction. As each succeeding portion appeared it was grasped with fine Kocher's forceps which provided a fresh hold for further enucleation until the whole or almost the whole gland came away. There was never any appreciable hæmorrhage, the vessels being very small; only very occasionally it was necessary to crush a vessel of unusual size and ligature of vessels was never called for. The operation was completed by closing the skin wound with a few Michel's clips. The mortality of this operation had, up to the present, been nil; it was easily performed and the results had been most gratifying.

DISCUSSION.

Mr. H. Henry (Dublin), who had found that the difficulty in Cushing's nasal approach to the pituitary gland arose chiefly from the variations in the sphenoidal sinus, exhibited an instrument by which he had been able to overcome these difficulties. The instrument consisted essentially of a metal tube attached variably to an apparatus which gave a firm attachment to the hard palate. The tube was passed into the submucous resection wound and guided into position by observations with the X rays, the operation being conducted in the X ray room. When in position the pituitary could be attacked under direct vision by means of instruments similar to those used with the operating cystoscope.

Testicular Grafting.

Dr. Serge Voronoff (Paris) described the objects and technique of testicular grafting which he had now performed in 44 cases in the human subject. After much experiment he had now devised a method which ensured long survival of grafts of fresh chimpanzee testicle into the human tunica vaginalis testis. The results of this method employed since 1920 had been both marked and, up to the present, permanent. The phenomena observed were a lowered blood pressure, reduction of weight in obese subjects, better vision in hypermetropes as the result of improved elasticity of the lens, new growth of hair, and improved muscular power and mental activity. To obtain such results it was necessary to use the testicles of monkeys of full growth and unmistakable virility; where the testes of young monkeys, in whom the internal secretion was not developed, were used no benefit had accrued. This proved that the results were not born of auto-suggestion. He appealed to other surgeons to try the operation when he was convinced they would realise its value.

Mr. Ivor Back (London) had seen Dr. Voronoff's work at Paris and talked with his patients, most of whom were themselves medical men, and was convinced of the value of testicular grafting. The effects of the removal of the testicular secretion by castration were well-known and the restoration of the internal secretion of the testes could, and did, restore many of the functions which decayed with age. The difficulty had been to find a suitable place where the grafts would survive. If placed under the skin or in the peritoneum they were absorbed, but with Dr. Voronoff's present method of implanting the grafts into the scarified tunica vaginalis, where each was anchored by a suture, they survived long enough to obtain a blood-supply; histological proof of this survival was obtained. The chimpanzee was selected as the donor on account of its close relationship to man; the excised testicle was cut into six segments and three were implanted into the interior of the tunica vaginalis of each testicle of the recipients. It was found that grafts of this size became vascularised in about 48 hours and survived. If smaller grafts were used they were absorbed and if larger they were apt to undergo necrosis at least in part.

Thyroid Transplantation.

Dr. A. Kocher (Berne), who had performed thyroid transplantation in 214 cases with only 14 per cent. of failures, described the operation as suitable, in the words of his late father, Prof. Th. Kocher, "for slight cases of thyroid deficiency," and preferable to thyroid medication. The most refractory cases were those of congenital absence of the thyroid, but three out of ten of such cases were improved, in one case sufficiently to take a university degree. The method employed was to implant portions of human thyroid not larger than a cherry, taken preferably from the upper pole of an exophthalmic goitre, into the peritoneum, where they were fixed by suture, or into the medullary cavity of the tibia. Patients must take thyroid before and for a little while after operation or the graft would not survive, while about half the patients had to supplement with thyroid medication after the operation, although the quantity required was always much reduced.

Dr. Froell (Stockholm) described the histology of different varieties of goitre and their associated blood changes. He had found that the pH concentration was high in toxic and low in ordinary goitres.

Use of Insulin in Surgery.

Dr. F. G. Banting (Toronto) said that insulin could have no effect on diabetic gangrene, as this was the result of arterial change; the use of insulin would, however, render the subject sugar-free, and permit of operation for gangrene or for any acute condition, such as appendicitis in a diabetic subject.

Suprarenal Grafting.

Mr. F. C. Pybus (Newcastle-upon-Tyne) described a successful case of suprarenal grafting for Addison's disease. The patient, who had previously been discharged from hospital as incurable and on the point of death, made a striking recovery after having suprarenal (from a healthy adult who died of an accident) grafted into the subcutaneous tissues. The blood pressure rose, pigmentation disappeared, muscular power was restored, and the blood picture, which had previously been that of pernicious anæmia, returned to normal. The man was able to return to light work for three years, when the symptoms recurred, and a fresh grafting was performed; no traces of the original graft could be found at the second operation. A second case in which a suprarenal graft from a male was implanted into a female was unsuccessful, as were also two attempts to graft pancreas into the subjects of pancreatic diabetes, though in one of the latter cases there was a slight and transient lessening of the glycosuria.

Dr. Juracz (Posen) described the effect of stimulating doses of X rays on the suprarenals in a severe case of asthma. The patient, though not cured, was much relieved, and one attack was cut short by the use of the X rays. Attempts to benefit cases of exophthalmic goitre by destructive doses of X rays directed to the suprarenals had also been made, but with less success.

Pituitary Tumours.

Dr. Krinski (Warsaw) described his experience with these tumours, and Mr. A. J. WALTON (London) advocated the frontal approach as the only one by which reasonably good access could be obtained.

The nasal route gave insufficient access to tumours that were generally more intracranial than sella, and carried a risk of sepsis. If approached by Horsley's temporal route the operation was embarrassed by a number of cranial nerves and the internal carotid artery, whereas the frontal route gave excellent exposure when the tumour protruded (as it almost invariably did) in front of the optic chiasma. By this route he had removed pituitary tumours, he believed completely, in seven cases with three deaths following operation and one remote death. The remaining three cases were strikingly improved.

In the evening a reception was held by Sir William and Lady Macewen at the Royal Society of Medicine, in the course of which the President gave a popular lecture on the Growth of Bone.

(To be continued.)

Medical News.

UNIVERSITY OF LONDON: *King's College Hospital Medical School.*—The following awards have been made:—

Burney Yeo Scholarships: G. F. Taylor, Sidney Sussex Coll., Cambridge; M. E. Lampard, Corpus Christi Coll., Cambridge; J. W. Thornton, Magdalen Coll., Oxford; J. A. Eyres, Lincoln Coll., Oxford. Epsom College Scholarship: R. P. Ross, Gonville and Caius Coll., Cambridge. Senior Scholarship and Tanner Prize for Obstetric Medicine: W. P. H. Sheldon. Jelf Medal: F. Brockington. Todd Prize and Medal for Clinical Medicine: F. Brockington. Class Prizes: *Diseases of Children* and Orthopædic Surgery, W. P. H. Sheldon; Medicine, R. Cove-Smith; Surgery, H. C. Edwards; Obstetric Medicine, F. Brockington; Pathology, C. E. Newman; Forensic Medicine and Psychological Medicine, M. A. Paul; Hygiene, L. H Savin.

University College.—The following awards in the Faculty of Medical Sciences have been made: Bucknill Scholarship (1922), R. L. Midgley; Medical Entrance Exhibitions (1922), E. H. Madge and V. Freeman; Sharpey Scholarship, A. S. Parkes; Cluff Prize, G. F. H. McCormick; Schafer Prize, Dr. Katherine Coward; *Gold Medal* for Anatomy (Senior Class), G. F. H. McCormick; Silver Medal for Anatomy (Junior Class), H. Awrounin; Gold Medal for Physiology (Senior Class), G. F. H. McCormick; Silver Medal for Organic and Applied Chemistry (General Course), R. M. Sargent. Silver Medal for Pharmacology (General Course), Beatrice G. Smith.

UNIVERSITY OF OXFORD.—*Radcliffe Scholarship in Pharmacology.*—This scholarship has been awarded to Robert Benedict Bourdillon, sometime Fellow of University College.

Theodore Williams Scholarships.—The following awards have been made:—In Physiology: Ormond Alec Beadle, New College; in Human Anatomy: John Samuel Jerome, Christ Church; in Pathology: George Payling Wright, Exeter College.

Beit Fellowship.—John Maurice Hardman Campbell, New College and Magdalen College, chief clinical assistant in the Neurological Department at Guy's Hospital, has been elected by the trustees to a Beit Memorial Fellowship for Medical Research.

UNIVERSITY OF MANCHESTER: MEDICAL DEGREE DAY.—The Vice-Chancellor, Sir Henry Miers, on July 14th, in his address said that the professional training for medicine and surgery was so exacting that the medical student had little or no time for an acquaintance with research. Year after year new subjects were *added* to the curriculum, but nothing was ever taken away from it. No other degree course was so long or so expensive. *The time* available for many of the special subjects was so short that their study was necessarily somewhat perfunctory. The medical curriculum was made up of a whole series of incomplete fragments, because the general practitioner might be called upon in the course of his practice to face problems connected with any of them. The medical profession was the most responsible of all professions, and we could not afford to neglect any part of the curriculum. He thought that in future the universities might give to their old students "refresher courses" to which medical men in the district might come without too great a sacrifice of their time. The Dental Board had tried such an experiment last year in providing lectures by eminent specialists at several university centres, of which Manchester was one. There was no place in England where the opportunities of medical training were greater than they were at Manchester with a group of hospitals serving the needs of a dense population.

Degrees were granted and awards made as follows:—

M.D. EXAMINATION.

J. C. Bramwell (awarded gold medal), C. H. Broomhead, Eugenia R. A. Cooper (awarded gold medal), Georgiana M. Duthie (awarded commendation), Ruth E. C. Verney, W. H. Wood (awarded gold medal).

FINAL M.B., CH.B. EXAMINATION (OLD REGULATIONS).

Greta Lowe, Louis Magenstern, Leslie Morris, G. T. Robinson, G. B. Stenhouse, and Geoffrey Talbot.

FINAL M.B., CH.B. EXAMINATION (NEW REGULATIONS).

Arnold Brown, W. B. Bacon, *§Arthur Barlow, Bernard Bowman, §A. J. E. Cave, *‡Albert Coleman, Gordon Crompton, N. L. Edwards, W. E. Fildes, W. A. J. Fleming, ‡E. J. Foulds, ‡Allen Glenn, *‡§Marjorie A. Grant, Evelyn M. Holmes, §K. H. Jackson, A. M. Jones, H. M. Levy, Miles Parkes, Donald Ramage, *‡G. C. Sharp, Margaret Simcock, ‡Wilson Smith. §W. G. Southern, and †§L. J. Witts.

* Awarded second-class honours. † Awarded first-class honours.
‡ Distinction in Forensic Medicine.
§ Distinction in Hygiene and Preventive Medicine.

Obstetrics and Surgery.—William Broadhurst, Madge E. Heywood, Bertha Kahn, A. C. Kelly (distinction in Obstetrics), W. B. McKelvie, Gladys F. A. McLean, Marjorie M. O'Dea, R. W. Parker, W. M. Roberts, Marjorie Robinson, Kate B. Scott, Agnes Seaston, Marjorie Thompson, Sarah Walker, Jane M. Wilde, and Marjorie Youatt.

Obstetrics.—C. N. Aldred, V. F. Lambert, and Thomas Pierson.

Forensic Medicine.—Bessie E. Cook, R. W. Fairbrother, and Thomas Pierson.

Hygiene and Preventive Medicine.—C. N. Aldred, Bessie E. Cook, R. W. Fairbrother, Thomas Pierson, H. F. Shaw, and Robert Slater.

Surgery.—J. F. Bromley.

UNIVERSITY OF DURHAM.—At Convocations held recently the following degrees were conferred:—

Doctor of Medicine.—Neil R. Beattie, Douglas G. P. Bell, Thomas H. Bates, Oliver Colville, Samuel W. Davidson, Charles N. Gover, and Stanley Worthington.

Doctor of Medicine for Practitioners of Fifteen Years' Standing.—William H. Bennett, Philip H. G. Gosse, and William L. Hodge.

Master of Surgery.—Ruth Nicholson.

Bachelor of Medicine and Bachelor of Surgery.—Reginald Armstrong, Helen Austin, Monica F. Bell, William A. Brown, Katherine M. Cellan-Jones, George A. Fothergill, Irene B. M. Green, Phillis Hall, Robert E. Haswell, Gwendolen M. Hunton, Bernard R. Isaacs, Edward H. Jaques, John E. D. Miller, Louis Minski, Doris H. Motyer, Ian M. McLachlan, Francis G. Mundell, George C. Parkin, Georgena L. Philipson, Henry N. Popham, George C. E. Reffell, Leslie F. Richmond, Henry C. Rollin, William O. Rubidge, Evelyn M. Scott, Kathleen Shelton, William F. O. Taylor, Arthur Todd, Pieter J. G. de Vos, Hugh A. Wallace, Alexander J. Watson, and John C. Yeoman.

Bachelor of Hygiene.—Neil R. Beattie.

Diploma in Public Health.—Neil R. Beattie.

Licence in Dental Surgery.—Bernard Benjamin, Walter L. Fleming, George Johnson, Uel Magnus John, George J. S. Littlefield, Charles H. Miller, William Murray, George S. Page, and Bernard J. G. Phillips.

UNIVERSITY OF ABERDEEN.—The following degrees have been conferred:—

DOCTOR OF MEDICINE.

Douglas W. Berry (honours for thesis), James S. Anderson (commendation for thesis), Andrew Topping (commendation for thesis), Dorothy E. Bryant, Alexander C. Fowler, and Louise Tomory.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

With First-class Honours.—*Allan W. Downie, *Richard D. Downie, and *Alexander Lyall.

With Second-class Honours.—†Alexander G. Badenoch, William H. Harris, Charlotte S. Hendry, and †Ian W. Laing.

Ordinary Degree.—George M. Anderson, Margaret J. Anderson, James Burnett, Janet F. Burnett, Charles W. M. Cameron, Catherine J. Clark, John Clarke, Patrick G. Currid, Robert Davidson, Douglas Dean, Elizabeth A. Dunbar, Mary Esslemont, Eric C. Gordon, Murdo McKenzie Gunn, Eleanor M. Henderson, James S. Hutchison, Archibald J. Ironside, Eric J. Jolly, *Bernard W. MacDonald, Finlay* MacLean, †Florence J. Malcolm, John C. Milne, Hugh W. Mulligan, Robert G. Munro, Forbes R. Mutch, James H. Peters, Margaret J. Rennet, Ernest R. Sorley, John S. Taylor, Lily M. Watt, Francis L. Webster, Mabel Wilson, and Maude Wilson.

* Passed Final Professional Examination with much distinction.
† Passed Final Professional Examination with distinction.

DIPLOMA IN PUBLIC HEALTH.

Isobel C. Brown, Evelina I. Corbett, Thomas J. Davidson, George L. Duncan, Ethel E. M. Gray, Elizabeth G. McCurrach, Norman M. Maclennan, Alexander E. Reid, Harry E. Smith, Christina Stuart, Andrew Topping, and Alice M. Watt.

The following awards have been made:—The Struthers Medal and Prize in Anatomy, John W. Foster: "A Series of Preparations illustrating the Comparative Anatomy of the Temporo-mandibular Articulation." The Lizars Medal in Anatomy, John W. Foster, Arthur J. W. Wilkins (equal). The John Murray Medal and Scholarship (awarded to the most distinguished graduate in medicine (M.B., Ch.B.) of the year 1923), Alexander Lyall, M.A., Aberdeen.

Royal College of Surgeons of England.—A quarterly Council meeting was held on July 12th, with Sir Anthony Bowlby in the chair. The President announced that at a meeting of the Fellows on July 5th five Fellows were elected into the Council in the vacancies occasioned by the retirement in rotation of Sir Charters J. Symonds and Sir Herbert Waterhouse, by the deaths of Sir William Thorburn and Sir Charles Ryall, and by the resignation of Mr. F. F. Burghard. The result of the poll, at which 1052 Fellows voted, was as follows:—

	Votes.	Plumpers.
James Berry	612	6
George Ernest Gask	466	28
John Herbert Fisher	445	53
Percy Sargent	445	3
William Sampson Handley ..	433	8

The above were therefore elected and Mr. Handley becomes substitute member of Council for Mr. Burghard until July, 1929, and Mr. Sargent becomes substitute member of Council for Sir William Thorburn until July, 1930. Messrs. Berry, Fisher, Handley, Sargent, and Gask took their seats on the Council.—Diplomas in Public Health were granted, jointly with the Royal College of Physicians, to 19 candidates. Diplomas in Psychological Medicine were granted, jointly with the Royal College of Physicians, to eight candidates.

The following professors and lecturers were appointed for the ensuing year:—

Hunterian Professors.—Robert Lawford Knaggs: One lecture on Leontiasis Ossea and one lecture on Osteogenesis Imperfecta. William Sampson Handley: One lecture on General Peritonitis. Charles Max Page: One lecture on the Operative Treatment of Osteoarthritis. Kenneth Macfarlane Walker: One lecture on the Internal Secretion of the Testis. Alexander Fleming: One lecture on the Employment of Antiseptics in Local and General Infection. Geoffrey Jefferson: One lecture on Injuries of the Cervical Spine. Frank Cook: One lecture on Toxæmias of Pregnancy. William Edward Gallie: One lecture on an Experimental and Clinical Study of the Use of the Fibrous Tissues in the Repair of Anatomical Defects. Sidney Forsdike: One lecture on Cancer of the Cervix. Ranald Montagu Handfield-Jones: One lecture on Retro-peritoneal Cysts—their Pathology, Diagnosis and Treatment. Ralph St. Leger Brockman: One lecture on the Problem of Drainage in Acute Appendicitis. W. H. Ogilvie: One lecture on the Infections of the Upper Alimentary Tract.

Arris and Gale Lecturers.—Hugh Ernest Griffiths: One lecture on the Relation of Diseases of the Gall-bladder to the Secretion and Functions of the Stomach and Pancreas. Cecil Pembrey Grey Wakeley: One lecture on Some Actions of Radiations on Living Tissues. Victor Ewings Negus: One lecture on New Points in the Mechanism of the Larynx.

Erasmus Wilson Lecturer.—Samuel George Shattock: Six Demonstrations on Pathological Specimens in the Museum.

Arnott Demonstrator.—Sir Arthur Keith: Six Demonstrations on the Contents of the Museum.

Sir John Bland-Sutton was elected President, and Sir Berkeley Moynihan and Mr. H. J. Waring were elected Vice-Presidents for the ensuing year.

Royal Society of Arts.—The Council of the Society attended, on July 13th, at Clarence House, St. James's, when the Duke of Connaught, President of the Society, presented the Albert Medals of the Society to Sir David Bruce and Sir Ronald Ross "in recognition of the eminent services they have rendered to the Economic Development of the World by their achievements in Biological Research and the Study of Tropical Diseases."

Society for the Prevention of Venereal Disease.—At its annual meeting, held on July 13th, a resolution was unanimously carried accepting the Trevethin Report as a document supporting the six essentials of the policy of the Society—namely, that:—

1. A man who after exposure is properly and thoroughly disinfected by disinfectants of appropriate nature and strength, runs little risk of infection.
2. An intelligent man if furnished with reasonable instructions can, in favourable conditions, effectively disinfect himself.
3. The adoption of skilled disinfection (in disinfecting centres) is not to be recommended as part of any general system, for reasons of time, cost, and impracticability.
4. The instruction by medical officers of venereal disease clinics of male persons attending such clinics, in the preventive use of disinfectants, offers a useful means of educating the community.
5. There is no evidence of facts in support of the view that any system of disinfection would tend to increase the number of exposures and raise the disease rate.
6. The law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants, provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority.

In view of the unqualified acceptance of the Trevethin Report by the National Council for Combating Venereal Disease, the Society is prepared to form a joint committee with the National Council, under the chairmanship of Lord Dawson of Penn, to watch and further the policy based on the terms of the Trevethin Report.

Royal Northern Hospital, London.—The foundation-stone of the new casualty department, which constitutes the Borough of Islington war memorial, was laid by Lady Patricia Ramsay on July 12th.

Extension of Blackburn Royal Infirmary.—The complete scheme for this institution, which serves North-East Lancashire, is estimated to cost £200,000. It has been decided to begin with an extension involving an expenditure of £75,000. This extension is intended as the town's war memorial.

London Hospital Medical College.—A lecture for senior students of the hospital and post-graduates on the Treatment of Puerperal Sepsis (a new method illustrated by charts) will be given by Dr. S. Gordon Luker on Tuesday, July 24th, at 4.15 P.M., in the Anatomical Theatre of the College.

London School of Tropical Medicine.—As a result of examinations held at the end of this session the "Duncan" medal has been awarded to Dr. S. Peterson of the U.S. Navy. Those who passed the examinations with distinction include Dr. A. H. Baldwin, Dr. F. McCallum, Dr. S. Pampana, Dr. A. Salama, and 34 candidates satisfied the examiners.

Royal Sussex County Hospital.—Recent developments at this hospital at Brighton include the new building for the orthopædic department, the money for which was largely given by the British Red Cross Society; the gift by Lady George Nevill, in memory of her husband, Lord George Nevill, who at one time was a member of the board of management, of the whole of the equipment of her war-time hospital at Hove; and the establishment, thanks to Miss Poulter, of a school of massage at the hospital.

The Lunatic Asylums in Burma.—The construction of a third asylum is projected to relieve the congestion at present experienced in one of the two existing buildings in Burma. There is evidence in the report that excellent facilities are provided for the employment and entertainment of the patients. Alcohol and *Cannabis indica* appear to take a large share in the ætiology of insanity in Burma; general paralysis is comparatively rare. Many of the deaths were due to pulmonary tuberculosis. During an outbreak of plague in Rangoon all the patients in the asylum received protective inoculations. No cases of the disease occurred in the asylum.

Small-pox Precautions in Territorial Training Camps.—A statement has been issued by the Ministry of Health to the effect that, in view of the prevalence of small-pox in certain parts of the country, he has been in communication with the Army Council in regard to the precautions in connexion with the annual training camps of the Territorial Army and Officers Training Corps. No units will be sent to camp from an infected district, but units raised in a non-infected district may be sent to camp in a non-infected district. All men will be examined by an army medical officer before proceeding to camp, and during the camping period any unvaccinated men will be kept under observation.

Free State County Councils and Health Reform.—At the annual meeting last week of the general council of county councils—a consultative body in which all the county councils in the Free State participate—the report of the standing committee on health matters was adopted. The report demands a series of legislative reforms in regard to health; though a separate Ministry of Health is favoured, its immediate establishment is not pressed. It is suggested that a health council should be constituted representative of the medical and allied professions, local health authorities, insured persons, labour and other organisations concerned, and the Ministry of Education. It was considered that the minimum health unit should be the administrative county or county borough. The committee also recommended the repeal of the Medical Charities Act, the extension of medical benefit to insured persons and their dependents, and the provision of medical treatment for those unable to pay for it. They recommended the establishment of a medical service paid by the State. The committee also recommended that tuberculosis and all infectious and contagious diseases dangerous to health should be notifiable, and that the tuberculosis medical officer should be empowered compulsorily to isolate persons in cases where he considers isolation essential in the interests of public health. Other recommendations included the effective inspection of cattle in respect of bovine tuberculosis and the application of the tuberculin test to the milk-supply. It was further recommended that for every health area there should be a medical officer of health, a veterinary officer, and that there should be provision for the effective inspection of school-children. Almost all the recommendations of the Irish Public Health Council have been adopted.

Parliamentary Intelligence.

HOUSE OF COMMONS:

WEDNESDAY, JULY 11TH.

Cost of Pensions Patients.

Mr. ALBERT ALEXANDER asked the Minister of Pensions what was the average cost per day of pensions patients at hospitals which were under the direct control of the Ministry of Pensions.—Major TRYON replied: The average is 8*s.* 2½*d.* per patient.

Small-pox and Vaccination.

Mr. BECKER asked the Minister of Health how many cases of small-pox had been notified this year; how many deaths had occurred from small-pox this year; and was he satisfied that all cases notified as small-pox were small-pox, or had any cases so notified been found to be chicken-pox.—Mr. NEVILLE CHAMBERLAIN replied: The number of cases of small-pox notified this year up to June 30th is 1225. No deaths had been registered up to the end of last week as due to small-pox, but I understand that a fatal case occurred at Gloucester with an unvaccinated child on the 8th inst. As regards the last part of the question, I am advised that, in small-pox as in other infectious diseases, errors in the initial diagnosis have occurred in some cases, but the notification returns are corrected from time to time by the omission of those cases which after notification have been found to be cases of chicken-pox, and the addition of cases originally diagnosed as chicken-pox but subsequently found to be cases of small-pox.

Mr. BROAD asked the Minister of Health if he would supply particulars of the cases of small-pox and deaths from that disease in the city of Mexico during each of the last 10 years for which figures were available.—Mr. NEVILLE CHAMBERLAIN replied: I have no information as to the number of cases of small-pox in Mexico city. The following are the particulars available in my department of the number of deaths from that disease in the city during each of the years 1913–1922: 1913, 326; 1914, 259; 1915, no figures available; 1916, 246 (10 months): 1917, 479; 1918, 140; 1919, 12; 1920, 40; 1921, 429; 1922, 404 (10 months).

Lieut.-Colonel FREMANTLE asked the Minister of Health if he would consider the transference of the administration of vaccination to the general sanitary administration under the sanitary authorities.—Mr. NEVILLE CHAMBERLAIN replied: This question has been under consideration, but I could not undertake to introduce the necessary legislation during the present session.

Sir GEORGE BERRY asked the Minister of Health if he was satisfied with the manner in which the Vaccination Acts were being administered: and, if not, if he was prepared, in view of the present serious epidemic of small-pox, to take steps to enforce rigid compliance with them.—Mr. NEVILLE CHAMBERLAIN replied: The responsibility for the administration of the Vaccination Acts rests with the boards of guardians and their vaccination officers. I am not satisfied that the Acts are being properly administered in all districts, and I am considering what steps can be taken to secure improvement in this respect.

Mr. BROMFIELD asked the Minister of Health whether the organism of vaccinia had yet been isolated; and, if not, what guarantee could be given that it was present in any given sample of calf lymph issued by his department for public vaccination purposes.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the negative. As regards the second part, I am advised that the efficacy of the lymph issued from the Government lymph establishment is adjudged by the usual laboratory tests for purity and its effect as reported by public vaccinators. I may add that the Government lymph used during 1922 for 284,000 cases of primary vaccination gave a percentage success of 99·4.

Mr. LEACH asked the Minister of Health if he would supply particulars of the cases of small-pox and deaths from that disease in Rio de Janeiro during each of the last 10 years for which the figures were available.—Mr. NEVILLE CHAMBERLAIN replied: The following are the particulars required by the hon. Member:—

Year.	Cases.	Deaths.	Year.	Cases.	Deaths.
1913	625	118	1918	—*	222
1914	5192	1230	1919	—*	305
1915	826	258	1920	324†	99
1916	119	121	1921	187†	49
1917	1530	418	1922	327‡	117

* Figures not available.

† 4 weeks missing. ‡ 3 weeks missing.

Mr. BROMFIELD asked the Minister of Health whether the glycerinated calf lymph manufactured by the Government was tested on a certain number of children before being issued to the public vaccinators, with a view to ascertaining whether it was satisfactory; and, if so, whether the consent of the parents of the children was obtained before these experimental vaccinations were carried out.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the negative, and the second part, therefore, does not arise.

Brook Fever Hospital.

Sir KINGSLEY WOOD asked the Minister of Health whether the Brook fever hospital at Shooters Hill was about to be permanently closed, and whether he could state the reason for this course.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the negative. I understand that, owing to the reduction in the number of cases of infectious disease in London, further admissions to this hospital are being stopped for the present, but the hospital will be reopened as soon as it is needed.

Medical Aid Departments.

Mr. CLARRY asked the Minister of Health if he could see his way clear to framing regulations whereby a friendly society or group of societies might form medical aid departments for the purpose of supplying medicines and surgical appliances to their members.—Mr. NEVILLE CHAMBERLAIN replied: The object which the hon. Member has in view cannot be secured without amending legislation which would be of a controversial character, and which I do not see my way to introduce. I have no power to deal with the matter by way of regulations.

Dirty Milk Vans.

Sir ARTHUR CHURCHMAN asked the Minister of Health whether his attention had been called to the lack of clean and well-ventilated milk vans on certain railway lines noted in paragraphs 42 and 43 of the interim report on milk issued by the departmental committee on the distribution and prices of agricultural produce; and whether his department proposed to take any action in the matter.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. I propose to ask my right hon. friend, the Minister of Transport, to bring the recommendations of the departmental committee to the notice of the railway companies.

Panel Practitioners' Remuneration.

Sir KINGSLEY WOOD asked the Minister of Health whether, in accordance with the pledge given by his predecessor, he proposed to consult both the Consultative Council and representatives of the approved societies before any new terms as to remuneration and service were arranged with the medical men on the panel lists; whether he proposed to arrange such consultation before any offer as to remuneration was made; and when, and in what manner, he proposed any consultation should take place.—Mr. NEVILLE CHAMBERLAIN replied: As regards the first two parts of the question, I would refer the hon. Member to the answer which I gave him on April 11th. As regards the third part, the matter is now under consideration, and I am not yet in a position to make any statement.

Discharge of Private Lunacy Patients.

Mr. HAYDAY asked the Minister of Health by what authority the London County Council, through their asylum regulations, had interfered with the right guaranteed to a petitioner by Section 72 of the Lunacy Act, 1890, to direct the discharge or transfer of a private patient from a pauper asylum by exacting four weeks' payment if the patient was taken away, whereas in institutions for rich patients the provisions of Section 72 were punctiliously carried out and the patient was allowed to leave at once on the legal direction given by his petitioners; and would he see that this practice was stopped.—Mr. NEVILLE CHAMBERLAIN replied: Inquiry is being made by the Board of Control and I will communicate the result to the hon. Member.

Deaths from Tuberculosis.

Mr. MURNIN asked the Minister of Health the number of persons who died in England and Wales during the years 1921–22 from tuberculosis.—Mr. NEVILLE CHAMBERLAIN replied: The number of deaths from tuberculosis in England and Wales during the year 1921 was 42,678, and during the year 1922 42,777.

Cheese, Milk, and Cream Standards.

Mr. HURD asked the Minister of Health the result of his consultation with the Minister of Agriculture with a view to the adoption of the recommendations of the departmental committee for the imposition of a legal minimum standard of quality applicable to whole-milk cheese, cream, and milk powder.—Mr. NEVILLE CHAMBERLAIN replied: I understand that my right hon. friend is examining the situation with a view to determining whether it is practicable to give effect to the recommendations of the departmental committee in regard to whole-milk cheese and cream.

Thursday, July 12th.

Medical War Records.

Mr. **Ede** asked the Minister of Pensions what progress had been made with the preparation of the medical records of the war, what sum had been expended on these records up to June 30th, 1923; when it was anticipated that the record would be completed; and what would be the total cost of the same.—Major **Tryon** replied: I assume that the hon. Member is referring to the records of admissions to and discharges from ambulances, hospitals, or clearing stations during service. These medical records have now been sorted and indexed in one register, but as the work was commenced by the War Office and completed by the Statistical Division of my department as part of their general duties, I regret I am not in a position to state the cost without very considerable investigation.

Treatment for War Neurosis.

Mr. **Robert Richardson** asked the Minister of Pensions what was the total number of pensioners receiving treatment for war neurosis and other shell-shock conditions, and whether he was satisfied with the provision made in the different regions for the treatment of pensioners suffering from shell-shock and/or neurasthenia.—Major **Tryon** replied: The number of patients at present receiving treatment under my department for war neurosis is about 6900. The whole question of the treatment of this very difficult condition is kept constantly under review by my medical advisers. Full provision is made for the most modern treatment. I am glad to say that our accommodation is ample and we have no waiting list.

Final Pension Appeals in 1921.

Mr. **Whiteley** asked the Minister of Pensions what number of cases were dealt with before the final tribunals in 1921 and 1922 for entitlement and assessment, respectively, and the number of successful cases in each year.—Major **Tryon** replied: The number of appeals on entitlement decided by the tribunal during 1921 was 43,750, of which 11,500 were allowed. The comparative figures for 1922 are 37,350 and 9,980. The assessment tribunals, which did not commence work until June, 1922, decided 13,023 appeals up to the end of that year. Of these the assessment was increased in 2500 cases and lowered in 23. The final award was set aside in 2500 cases and the appeal disallowed in 8000 cases.

Institutional Treatment of Tuberculosis.

Mr. **Trevelyan Thomson** asked the Minister of Health whether he approved of the charge made to tuberculous persons in the London area in respect of institutional treatment; and, if so, why, in this respect, had the institutional treatment of tuberculous persons been differentiated from that of the other infectious diseases.—Lord E. **Percy** replied: My department have approved generally of the arrangement made by the L.C.C. for the assessment of contributions payable by tuberculous persons towards the cost of institutional treatment provided by the Council. As regards the second part of the question, the statutes under which institutional treatment is provided in London for persons suffering from other infectious diseases do not authorise the recovery of any part of the cost of treatment from the patient.

Wounds on Executed Prisoner.

Mr. **Lansbury** asked the Secretary of State for the Home Department whether his attention had been called to the fact that at the inquest held on Roland Duck, after his execution at Pentonville prison last week, a severe wound was found on his head and a considerable quantity of congealed blood was attached to his hair; whether the coroner had made a report to him as to how this injury was sustained; and whether the man's father and mother, who attended the inquest, had asked the Home Office to order an inquiry as to the cause of this injury.—Mr. **Bridgeman** replied: Reports received from the prison showed that when the body was taken down there was no mark on the head, but when the body was being washed, after removal to the mortuary and post-mortem examination of the neck by the medical officer, a bruise was noticed on the forehead. The body had slipped while being placed on the mortuary table and the head had struck a slab. The medical officer called the coroner's attention to the bruise. The coroner's inquisition was sent to me. He made no report, but I have now seen his notes, which show that the jury was satisfied that the bruise was caused after the execution. Before the inquest ended the father said he was satisfied, but both parents have written since expressing dissatisfaction. They will be informed that I find no ground for further inquiry.

Infection in Public Libraries.

Colonel **Morden** asked the Minister of Health whether his attention had been directed to the danger of infection to the frequenters of public libraries through the use of books previously handled by persons suffering from infectious ailments; and whether he would take steps to investigate this menace to the public health by directing local authorities to use adequate disinfectants in the public libraries of this country.—Lord E. **Percy** replied: The answer to the first part of the question is in the affirmative, but my right hon. friend is advised that medical officers of health are fully alive to whatever danger of infection there may be from this source. Special provisions as to the precautions to be taken to prevent the spread of infection through the use of library books are contained in Section 59 of the Public Health Acts Amendment Act, 1907, and that section may be put in force in any district on the application of the local authority. In the circumstances the Minister does not consider it necessary to undertake any special investigation or to issue any special instructions to local authorities on this matter.

Fifty per Cent. Pension Awards.

Mr. **Herriotts** asked the Minister of Pensions the number of pensioners in receipt of a pension of 50 per cent. or over on March 31st, 1919, and the number of pensioners in receipt of a pension of 50 per cent. or over on March 31st, 1923, for loss of vision, for loss of limbs, for loss of hearing, for gunshot wounds, for tuberculosis, and for diseases other than tuberculosis respectively.—Major **Tryon** replied: The answer to the first part of the question is 252,000. In March, 1923, approximately 160,800 awards of 50 per cent. or over were in payment as follows: Eye disabilities 6600, injury to limbs (including amputations) 58,000, other wounds and injuries 22,800, ear disabilities 2800, tuberculosis 30,300, other diseases 40,300.

Small-pox and Vaccination.

Mr. **Trevelyan Thomson** asked the Minister of Health the particulars which indicated that the percentage of cases of small-pox had increased with the reduction in the number of vaccinations which had fallen from 85·6 of births in 1872–81 to 43·4 in 1912–21.—Lord E. **Percy** replied: As my right hon. friend informed the hon. Member on the 4th inst., particulars as to the total number of cases of small-pox in England and Wales are not available for any year prior to 1911, and it is not, therefore, possible to give the desired information for the periods mentioned in the question. The number of cases of small-pox during each of the years 1911 to 1922, and the percentage of vaccination to births in each of those years, are given in the following table:—

Year.	Cases of small-pox.	Percentage of vaccination to births.	Year.	Cases of small-pox.	Percentage of vaccination to births.
1911	289	52·3	1917	7	42·3
1912	121	50·1	1918	63	41·5
1913	113	46·5	1919	311	40·6
1914	65	44·6	1920	280	39·5
1915	93	45·5	1921	336	38·3
1916	159	44·7	1922	973	—*

* Not yet available.

White Lead Convention.

On a vote of £185,969 for the salaries and expenses of the Home Office,

Mr. A. **Greenwood** moved to reduce the vote by £100. He said there were far too many cases of lead poisoning at the present time, and he attributed that to the ineffective administration of the regulations by the Home Office. The whole industry was united, and there was no real reason which should debar the Home Secretary from enforcing on the Cabinet the importance of an early ratification of the White Lead Convention.

Mr. **Turner** seconded.

Mr. G. **Locker-Lampson** (Under-Secretary for the Home Department) said the question of ratifying the White Lead Convention agreed upon at Geneva was not quite so easy as some people might think. The Minister of Labour who was at Geneva agreed to the terms of the agreement, but unfortunately since that date a certain misunderstanding had arisen about one of the principal agreements under the Convention—the employment of young persons under 18 and the employment of women for industrial purposes. Apparently a good many members at Geneva were under the impression that that article referred only to the painting of houses. Other members declared that it referred to the whole of industrial painting. Until that point had been cleared up satisfactorily it was rather difficult for this country to agree to the ratification of the Convention. He hoped, however, the delay would not be very long. Since the Geneva Convention sat a new process had been introduced involving the use of wet sand-paper, by means of which the old dangers arising out of dry rubbing down could be prevented. He thought it was absolutely essential that further experiments should be made with this new material before a definite decision was come to. The Home Office was at present receiving deputations on the subject.

Workmen's Compensation.

Mr. G. SPENCER asked whether the Home Secretary would appoint another medical referee under the Workmen's Compensation Act for the County of Nottingham for dealing with certain industrial diseases. At the present time cases had to be sent to Sheffield, and the men affected had to pay their expenses to Sheffield to be examined in cases in which the certificate given by the certifying surgeon was questioned by a colliery company. He was sorry to say that the workmen in the county of Nottingham had lost faith in the present medical referee, not because they alleged he was unfair, or that he acted in an *ex parte* manner, but because they believed that he was not conducting cases consistently with the description of the disease in the Act. He belonged to the school of medical opinion which held that if objective symptoms were not present, then the disease did not exist.

Mr. LOCKER-LAMPSON said that the point raised by Mr. Spencer was an important one, and the Home Office would consider it.

The motion to reduce the vote was negatived and the vote was agreed to.

FRIDAY, JULY 13TH.

Sale of Liquor to Children.

On the motion for the third reading of the Intoxicating Liquor (Sale to Persons under 18) Bill,

Sir F. BANBURY moved the rejection of the measure. He said he wished to call the attention of Viscountess ASTOR and a number of those who supported the Bill to a speech made by Sir S. Russell-Wells only a few days previously, in which he said that beer was a food and contained a certain quantity of nourishment, and also that tea was a pure drug. Therefore the supporters of the Bill were endeavouring to prevent young people from getting what a medical authority declared to be nourishment and to make them take instead *something* which was after all merely a drug.

Viscountess ASTOR thanked the Government for having given facilities to the Bill.

The Bill was read a third time by 257 votes to 10.

Small-pox and Vaccination.

Lieut.-Colonel ARTHUR MURRAY asked the Minister of Health whether he could state how many of the 408 persons noted as suffering from small-pox for the four weeks ended June 30th were vaccinated at birth and/or were vaccinated at a later period.—Mr. CHAMBERLAIN replied: Information as to the vaccinal condition of these persons is at present available in only 227 of the cases. This information is given in the following statement, but the particulars are subject to revision in the light of further information which may subsequently be received:—

Unvaccinated.	Vaccinated in infancy.	Vaccinated later.		Revaccinated.	Stated to have been vaccinated but showing no cicatrix of vaccination.
		After infancy and before exposure to infection.	After exposure to infection.		
188	31*	1	3	2	2

* Including 2 suspected cases.

Institutional Treatment of Tuberculosis in Leicester.

Major GUY PAGET asked the Minister of Health whether he was aware that the cases for Government treatment for tuberculosis were limited in Leicester to 30; and, seeing that, in view of the fact that every insured person contributed to this treatment, this was an insufficient number, and that in consequence the voluntary institution was overcrowded with surgical tuberculous cases which largely hampered its other work, would he inquire into the matter. —Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the negative. On July 1st the number of persons receiving institutional treatment for tuberculosis from the Leicester Town Council was 217. I am not aware of the actual number of cases of [illegible] tuberculosis included in this figure, but the provision [illegible] by local authorities for the treatment of this [illegible] naturally have the effect of relieving the [illegible] voluntary institutions. In the [illegible] necessity for any special inquiry, and I [illegible] the health insurance contributio[illegible] persons do not now include any [illegible] of institutional treatment for [illegible]

MONDAY, JULY 16TH.

Child Mortality.

Mr. WILLIAM THORNE asked the Minister of Health the number of children who died before the age of 12 months in the London County Council area, Glasgow, West Ham, and Stoke-on-Trent during the year ending March, 1922.—Lord E. PERCY replied: The figures asked for in the question as regards London are 8334; Glasgow, 3644; West Ham, 705; and Stoke-on-Trent, 978. The corresponding infant death-rates per 1000 births for London, West Ham, and Stoke-on-Trent were 82, 83 and 138 respectively.

Insulin Treatment.

Sir WALTER DE FRECE asked the Minister of Health what steps were being taken to bring the insulin treatment within the reach of the very poor.—Lord E. PERCY replied: It is within the powers of guardians, on the advice of the medical officer, to pay for the supply of insulin in cases of destitution.

Pensions Administration in the North of England.

Mr. POTTS asked the Minister of Pensions whether the Yorkshire regional headquarters of the Ministry of Pensions were to be transferred to Newcastle; whether he would state the population in the present Yorkshire area and the population in the northern area which was at present administered from Newcastle; whether the population in the Yorkshire area was approximately nearly double that of the northern; and, if it was eventually intended to administer the entire North of England from one centre, would he consider whether Leeds would offer a balance of advantages.—Captain CRAIG replied: The answer to the first part of the question is in the affirmative; to the second and third parts, that the population of the Yorkshire and northern regions, according to the census of 1921, is 3,917,713 and 2,754,487 respectively; and to the last part that it is not in contemplation to administer the entire north of England from one centre.

Child Adoption.

Mr. GERALD HURST asked the Secretary of State for the Home Department whether he had considered the Report on child adoption made by the committee appointed to make such Report by the Home Office and the two Bills which had been introduced to give effect to its recommendations; and if he could hold out any hopes of the Government bringing in or giving facilities to any Bill for this purpose.—Mr. BRIDGEMAN replied: Yes, Sir. I am afraid the Government cannot undertake to introduce legislation on this subject at the present time, and the pressure of Parliamentary business makes it impossible to give special facilities to a private Member's Bill.

Infantile Mortality.

Captain BOWYER asked the Minister of Health whether he would give the most recent figures showing the death-rate per 1000 of legitimate and illegitimate infant children, respectively; and would he say how these figures compared with those of ten years ago.—Mr. NEVILLE CHAMBERLAIN replied: The most recent figures are those for 1922, in which year the infant death-rate per 1000 children born was 74 in the case of legitimate children and 139 in the case of illegitimate children. The corresponding figures for the year 1912 were 91 and 181 respectively.

Dentists Bill.

The Dentists Bill was read a third time. (The object of this measure is to give ex-Service students of the dental profession extra time to qualify under the provisions of [illegible] 1921 Act.)

TUESDAY, JULY 17TH.

Visiting Committees in Mental Hospitals.

Mr. WILLIAM ALBERT JENKINS asked [illegible] Health if he was aware that at present [illegible] have not the right of full representation [illegible] committees of mental hospitals; and [illegible] make provision for this right [illegible] Parliament.—Lord E. PERCY [illegible] first part of the question [illegible] it is desirable to give [illegible] suggested.

[illegible]

view to determining whether it is practicable to give effect to the recommendations of the departmental committee in regard to whole-milk cheese and cream.

THURSDAY, JULY 12TH.

Medical War Records.

Mr. EDE asked the Minister of Pensions what progress had been made with the preparation of the medical records of the war, what sum had been expended on these records up to June 30th, 1923; when it was anticipated that the record would be completed; and what would be the total cost of the same.—Major TRYON replied: I assume that the hon. Member is referring to the records of admissions to and discharges from ambulances, hospitals, or clearing stations during service. These medical records have now been sorted and indexed in one register, but as the work was commenced by the War Office and completed by the Statistical Division of my department as part of their general duties, I regret I am not in a position to state the cost without very considerable investigation.

Treatment for War Neurosis.

Mr. ROBERT RICHARDSON asked the Minister of Pensions what was the total number of pensioners receiving treatment for war neurosis and other shell-shock conditions, and whether he was satisfied with the provision made in the different regions for the treatment of pensioners suffering from shell-shock and/or neurasthenia.—Major TRYON replied: The number of patients at present receiving treatment under my department for war neurosis is about 6900. The whole question of the treatment of this very difficult condition is kept constantly under review by my medical advisers. Full provision is made for the most modern treatment. I am glad to say that our accommodation is ample and we have no waiting list.

Final Pension Appeals in 1921.

Mr. WHITELEY asked the Minister of Pensions what number of cases were dealt with before the final tribunals in 1921 and 1922 for entitlement and assessment, respectively, and the number of successful cases in each year.—Major TRYON replied: The number of appeals on entitlement decided by the tribunal during 1921 was 43,750, of which 11,500 were allowed. The comparative figures for 1922 are 37,350 and 9,980. The assessment tribunals, which did not commence work until June, 1922, decided 13,023 appeals up to the end of that year. Of these the assessment was increased in 2500 cases and lowered in 23. The final award was set aside in 2500 cases and the appeal disallowed in 8000 cases.

Institutional Treatment of Tuberculosis.

Mr. TREVELYAN THOMSON asked the Minister of Health whether he approved of the charge made to tuberculous persons in the London area in respect of institutional treatment; and, if so, why, in this respect, had the institutional treatment of tuberculous persons been differentiated from that of the other infectious diseases.—Lord E. PERCY replied: My department have approved generally of the arrangement made by the L.C.C. for the assessment of contributions payable by tuberculous persons towards the cost of institutional treatment provided by the Council. As regards the second part of the question, the statutes under which institutional treatment is provided in London for persons suffering from other infectious diseases do not authorise the recovery of any part of the cost of treatment from the patient.

Wounds on Executed Prisoner.

Mr. LANSBURY asked the Secretary of State for the Home Department whether his attention has been called to the fact that at the inquest held on Roland Duck, after his execution at Pentonville prison last week, a severe wound was found on his head and a considerable quantity of congealed blood was attached to his hair; whether the coroner had made a report to him as to how this injury was sustained; and whether the man's father and mother, who attended the inquest, had asked the Home Office to order an inquiry as to the cause of this injury.—Mr. BRIDGEMAN replied: Reports received from the prison showed that when the body was taken down there was no mark on the head, but when the body was being washed, after removal to the mortuary and post-mortem examination of the neck by the medical officer, a bruise was noticed on the forehead. The body had slipped while being placed on the mortuary table and the head had struck a slab. The medical officer called the coroner's attention to the bruise. The coroner's inquisition was sent to me. He made no report, but I have now seen his notes, which show that the jury was satisfied that the bruise was caused after the execution. Before the inquest ended the father said he was satisfied, but both parents have written since expressing dissatisfaction. They will be informed that I find no ground for further inquiry.

Infection in Public Libraries.

Colonel MORDEN asked the Minister of Health whether his attention had been directed to the danger of infection to the frequenters of public libraries through the use of books previously handled by persons suffering from infectious ailments; and whether he would take steps to investigate this menace to the public health by directing local authorities to use adequate disinfectants in the public libraries of this country.—Lord E. PERCY replied: The answer to the first part of the question is in the affirmative, but my right hon. friend is advised that medical officers of health are fully alive to whatever danger of infection there may be from this source. Special provisions as to the precautions to be taken to prevent the spread of infection through the use of library books are contained in Section 59 of the Public Health Acts Amendment Act, 1907, and that section may be put in force in any district on the application of the local authority. In the circumstances the Minister does not consider it necessary to undertake any special investigation or to issue any special instructions to local authorities on this matter.

Fifty per Cent. Pension Awards.

Mr. HERRIOTTS asked the Minister of Pensions the number of pensioners in receipt of a pension of 50 per cent. or over on March 31st, 1919, and the number of pensioners in receipt of a pension of 50 per cent. or over on March 31st, 1923, for loss of vision, for loss of limbs, for loss of hearing, for gunshot wounds, for tuberculosis, and for diseases other than tuberculosis respectively.—Major TRYON replied: The answer to the first part of the question is 252,000. In March, 1923, approximately 160,800 awards of 50 per cent. or over were in payment as follows: Eye disabilities 6600, injury to limbs (including amputations) 58,000, other wounds and injuries 22,800, ear disabilities 2800, tuberculosis 30,300, other diseases 40,300.

Small-pox and Vaccination.

Mr. TREVELYAN THOMSON asked the Minister of Health the particulars which indicated that the percentage of cases of small-pox had increased with the reduction in the number of vaccinations which had fallen from 85·6 of births in 1872–81 to 43·4 in 1912–21.—Lord E. Notes, Comments, and Abstracts.

TYPHUS FEVER EPIDEMIC AMONG THE GREEK REFUGEES.

BY SIR PATRICK HEHIR, K.C.I.E., C.B., C.M.G., M.D. BRUX., F.R.C.S., F.R.C.P. EDIN.,
MAJOR-GENERAL, I.M.S. (RET.): MEDICAL ADVISER, BRITISH RED CROSS SOCIETY IN GREECE.

IT has fallen to my lot to see a great deal of typhus among the Greek refugees during the last four and a half months. As the outbreak presents many points of difference, epidemiologically and otherwise, from the disease as ordinarily met with elsewhere, an account of it may be of interest. The Greek refugees primarily brought the infection with them, and have been moving from one place to another carrying the disease, either in the incubating stage or in a mild ambulatory form. The serious cases are, of course, incapable of movement with the masses.

Epidemiology.

The epidemiological history of the present outbreak is easily understood if one pictures the conditions, economic, political, and military, that have been in existence in relation to these refugees since last autumn. Apparently there is a gradual rise in the intensity of the epidemic until it reaches its acme; this continues for a few months and then the epidemic gradually subsides. There are, however, oscillations in the intensity which, I believe, are mainly associated with variations in meteorological conditions, but doubtless other accidental factors are concerned. With us it began at the end of January, gradually rose in numbers and severity of attacks, reached a maximum about the first fortnight in March, remained stationary for a month or so, and is now undergoing a marked abatement.

It is noteworthy that in areas where refugees have been widely dispersed on the land there has been no typhus, or it has not become epidemic when introduced. Other things being equal, the intensity of the epidemic appears to depend largely upon the economic conditions in existence. The relation of typhus to overcrowding, long misunderstood, is now known to be easily explained by the part that human lice play in the disease. The brunt of the epidemic has been borne by the larger towns—e.g., Athens and its environs, Salonica, Patras, Corfu—the smaller towns escaping to a considerable extent, the incidence being related to the density of population on the occupied area. Whole rural districts in Macedonia and Western Thrace have escaped altogether. The housing conditions of the refugees, their hardships—especially insufficient food and exposure—have considerably lowered their resistance to disease, which, except in the case of minor maladies, runs a serious course and is frequently fatal. This high mortality is important, as it has aroused antipathy to the hospitals; early cases of sickness are hidden, and often hospital relief is only sought when the patient is dangerously ill, this being one of the ways in which typhus is being spread.

The outbreak attained its maximum of intensity in mid-winter. In colder weather the people are more crowded together: they wear thicker clothes, which foster lice, and bathe less frequently. Throughout the winter refugees were packed with the ordinary civil population in the waiting rooms of railway stations and in other places; contact cases were therefore more frequent. As I write this in the British Red Cross train at Salonica railway station, a refugee-train is in a siding; in and around the station yard are, roughly, 500 refugees, all on the way to Seres (Thrace) to take up work on the land. The same sort of arrivals and distributions are occurring in many large railway stations; it is easy to see how communicable disease spreads rapidly among them, and also reaches the stationary populations of towns.

Overcrowding is, however, only one of the factors that enter into the epidemiology of typhus. Other hardships exist: A very large percentage of the refugees get only a bare subsistence allowance of food. In some districts men who can work get no food dole, and out-of-work women get only 6 to 8 ounces of bread or flour a day. Until a few months ago few refugees had a change of clothing; undergarments were especially scarce. A great deal of help has been given them now in this respect, and I know of no camp of any duration that has not been relieved. With only one suit of clothes the practical difficulties of delousing are obvious; the suit is put through the steam disinfector and dried while the refugee is having his bath. The sanitary condition under which refugees lived for months after their return to Greece was indescribably bad: it has, in the last two months or so, been greatly ameliorated.

It is superfluous to state that the infected human louse is the intermediary in the transmission of typhus; ordinarily there is no direct communication of the disease from man to man. If it were possible to exterminate human lice in an infected area the disease would cease. All our radical preventive measures are based on this knowledge. Experienced local medical administrators act on the principle that if there are no lice on the people themselves and their clothes they cannot give the disease to others. Somehow it has got abroad that it is only the body-louse that acts as a carrier. I am all but morally certain that this is not the case, and that the exculpation of *P. capitis* is a dangerous theory.

The micro-organism of typhus passes through a developmental stage in the louse; in that insect it is intracellular, develops, is set free, and is finally discharged into the oral apparatus, from which it is introduced into man. In man it again becomes intracellular, and from the infected cells it is thrown into the blood with its toxins. The louse does not *transmit the virus until four days have elapsed from the time* of its infection; infection of man is in the vast majority of cases through the bite of the louse, and the insect's excreta rubbed into scratches of the skin is also believed to give rise to infection in a small number of cases. So far as I can discover, no original work is being done during this epidemic in regard to the relation of the louse to typhus.

The infectious diseases hospitals for typhus cases in refugees are not ideal institutions, but they might be worse. There is usually a sufficient number of sick attendants, nurses, and doctors, but want of experience as to how to deal with the disease has been evident in several local epidemics. The arrangements for protecting the hospital staff from infected lice was one of the most serious defects I came across. When I visited an infectious diseases hospital some weeks ago a long white coat was given me to wear in the wards. After I had put it on one of the hospital orderlies picked off a louse from the neck, remarking that it was seldom he found one on the assistant director's gown which I was wearing. In one infectious diseases hospital the arrangements for delousing patients admitted were of the most elementary kind, except that a steam-disinfector was occasionally used for the clothing when water was available. There was no bathing of patients on admission, but the hair was cut short. I found that the sanitary arrangements in wards and latrines called for serious improvement—some of the wards were offensive, as several cases of incontinence of urine and fæces were present and the nursing and cleanliness were unsatisfactory. In our own camp one day I found that three cases which the Greek medical officer (himself a refugee) had diagnosed as "fever" had been allowed to remain in the main blocks. All three had lice on their clothes; they were all cases of typhus and two of them already had the rash. In one town a severe epidemic of influenza was reported to exist, but the high mortality aroused suspicion and inquiries by experts were made; it was found that influenza was the minor disease and typhus the real epidemic. The same history was given me by the controlling medical authority in regard to two other towns. As the result of this want of experience several doctors and nurses taking no precautions got the disease and died. It is all but morally certain that anyone attending typhus cases without a knowledge of the nature of the disease will become infected himself sooner or later. It is important to educate the subordinate staff of these hospitals in the ætiology of typhus and the principles adopted in the prevention of infection.

(*To be continued.*)

MEDICAL WORK OF THE MISSION TO LEPERS.

THE forty-eighth annual report of the Mission to Lepers,[1] presented at the annual general meeting of members of the mission at the Central Hall, Westminster, on May 10th, contains a chapter devoted to the medical work of the mission, in which short statements by various medical men and women are quoted. The mission cares for 7735 leper inmates in its own and aided institutions, and also for over 600 untainted children, who are educated and trained in separate homes to become useful members of the healthy community. At Dichpalli, near Nizamabad, Deccan, India, improved results have been obtained by intravenous injection of the ethyl esters of chaulmoogra or hydnocarpus oils, as opposed to intramuscular injection. "This means that very much more of the drug is administered, with consequent signs of improvement. In nodular cases an auto-vaccine is prepared for each patient." In some cases the two methods are combined. The conditions of unrest in China militate against the handling of the leper problem: "In Siao Kan (Central China), since the middle of the war period, we have only encouraged the more pronounced, or chronic, cases to come into residence. This means that we have turned away

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, July 23rd.—10 A.M., Mr. Maingot: Surgical Pathology. 2 P.M., Mr. Addison: Surgical Wards. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10 A.M., Mr. Steadman: Dental Dept. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Dr. Burnford: Medical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 3 P.M., Dr. Scott Pinchin: Medical Out-patients.

FRIDAY.—11 A.M.; Dr. McDougal: Electrical Dept. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Demonstration of Clinical Cases at 3.30 P.M.

MONDAY, July 23rd.—Dr. J. Browning Alexander: Medical.

TUESDAY.—(3 P.M.) Mr. Howell Evans: Surgical.

WEDNESDAY.—Mr. Norman B. B. Fleming: Eye Cases.

THURSDAY.—Mr. H. W. Carson: Surgical.

FRIDAY.—Dr. C. E. Sundell: Diseases of Children.

Appointments.

ANDERSON, J. B., M.B., Ch.B Aberd., has been appointed District Medical Officer and Public Vaccinator for Bishopwearmouth, West District.

DAVIDSON, G. S., M.B. Aberd., F.R.C.S. Edin., to be Extra Physician (Honorary) to the Aberdeen Maternity Hospital, with special charge of the Out-patient Department.

DAVIES, J. C., M.B., B.Ch. Oxf., Certifying Surgeon under the Factory and Workshop Acts for the Chipping Campden District of the County of Gloucester.

GUEST, D., M.B., Ch.B., Assistant Bacteriologist, University of Sheffield.

LAMONT, D. C., M.B. Edin., D.P.H., Assistant Medical Officer of Health and Tuberculosis Officer; and FRAZER, W. M., M.Sc., M.B., Ch.B. Liverp., Assistant Medical Officer of Health and Assistant School Medical Officer at Blackburn.

M'KENDRICK, W., M.D. Glasg., D.P.H., Medical Officer of Health for Hartlepool.

M'KINNEY, J. W., M.B., Ch.B. Edin., D.P.H. Dub., Medical Officer of Health to the Ballymoney Urban District Council.

Queen Charlotte's Lying-in Hospital: CUTHBERT, J. R., M.B., Ch.B. Otago, N.Z., and HALL, N. B., M.B., B.S. Adelaide, Assistant Resident Medical Officers.

Vacancies.

For further information refer to the advertisement columns.

Canterbury, Kent and Canterbury Hospital.—Res. M.O. £175.

Cheshire Joint Sanatorium, Loggerheads.—A.M.O. £350.

Chesterfield and North Derbyshire Royal Hospital.—Jun. H.S., Cas. O. and Orthopædic H.S. £175 and £170 respectively.

Dreadnought Hospital, Greenwich, S.E.—H.P. £150.

Durham County Hospital.—H.S. £200.

Earlswood, Royal Earlswood Institution.—Med. Supt. £800.

East African Medical Service.—M.O. £600.

East London Hospital for Children.—H.P. £125.

Glasgow University.—Chair of Public Health.

Hemel Hempstead, West Herts Hospital.—Res. M.O. £200.

King's College Hospital, Denmark Hill, S.E.—Jun. Anæst.

King's Lynn, West Norfolk Hospital.—Asst. Res. M.O. £100.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

Liverpool, West Derby Union.—Asst. Res. M.O. £300.

London Hospital, E.—Second Registrar to Ear, Throat and Nose Dept. Also First Asst. to each of the Surgical Firms. £400.

Manchester, Baguley Sanatorium.—Third Asst. M.O. £400.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—Asst. Res. M.O. £100.

Manchester, Victoria Memorial Jewish Hospital.—Hon. S.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—Non-Res. H.S. £150.

Mid-Wales Counties Mental Hospital, Talgarth, Breconshire.—Med. Supt. £800.

Middleton-in-Wharfedale Sanatorium, Ilkley.—Res. A.M.O. £325.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Res. M.O. £150.

Northampton County Mental Hospital.—Locum. £8 8s. weekly.

Nottingham Children's Hospital.—Res. H.S. £150.

Rotherham Hospital.—Jun. H.S. £150.

Royal Naval Medical Service.—Surgeon-Lieutenants.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150.

St. Andrews University Medical School, Dundee.—Chair of Medicine.

St. Bartholomew's Medical College.—Demonstrator of Physiology.

Salvation Army Mothers' Hospital, Clapton.—Sen. Res. Med. Woman.

Tiverton Hospital, Devon.—H.S. £100.

West African Medical Service.—M.O. £660.

Windermere, Ethel Hedley Hospital for Crippled Children.—H.S. £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointment: St. Just (Cornwall).

Births, Marriages, and Deaths.

BIRTHS.

ALLCHIN.—On July 9th, at "The Briars, Northwick Park-road, Harrow, the wife of F. M. Allchin, M.B. Lond., of a son.

FIRTH.—On July 13th, at Manchester-square, W., the wife of Douglas Firth, M.D., of a daughter.

HOLMES.—On July 14th, at 29, Manley-road, Whalley Range, Manchester, to Dr. and Mrs. A. Hillyard Holmes, a daughter.

MOORHEAD.—On July 12th, at Little Squerryes, Westerham, the wife of R. Leishman Moorhead, M.B., C.M., of a daughter.

MARRIAGES.

BLOCKLEY—MYERS.—On July 10th, at St. John's Church, Torquay, John P. Blockley, F.R.C.S. Edin., to Effie, widow of James Nutter Myers.

EDEY—EWALD.—On July 9th, at Christ Church, Ramsgate, Thomas Hugh Edey, M.R.C.S., L.R.C.P., to Gladys Yarborough, younger daughter of the late Henry B. Ewald and Mrs. Ewald, of Nelson-crescent, Ramsgate.

DEATHS.

CODNER.—On July 12th, at Woodside, Corfe, near Taunton, John Codner, M.B., C.M. Edin.

PARE.—On July 13th, John William Pare, M.D., L.D.S. Eng., F.R.S. Edin., aged 62.

N.B.—A fee of 7s. 3d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ROYAL SANITARY INSTITUTE.—The thirty-fourth congress will take place at Hull from July 30th to August 4th, under the presidency of the Rt. Hon. T. R. Ferens, J.P., High Steward of Hull. The inaugural meeting will be held at the Royal Institution, Albion-street, on July 30th at 5 P.M. Sections will be devoted to sanitary science, personal and domestic hygiene, engineering and architecture, and maternity and child welfare (including school hygiene). There will be conferences of the following public health workers: representatives of sanitary authorities, engineers and surveyors, health visitors, port sanitary authorities, veterinary inspectors, and medical officers of health. The meetings of sections and conferences will be held in the School of Art, Anlaby-road, and in the Guildhall. On July 31st, at 8 P.M., Sir Alexander Houston will lecture on "A Pure Water Supply," and on August 2nd, at 8 P.M., Mr. B. Seebohm Rowntree will lecture on "Industry and National Welfare."

An exhibition of apparatus and appliances relating to health and of domestic use will be held, in connexion with the congress, at the Wenlock Barracks, Anlaby-road. Fellows, members, and associates of the Institute are supplied with tickets (£1 11s. 6d. each) on application to the Secretary before the congress, at the offices of the Institute, 90, Buckingham Palace-road, S.W. 1. Tickets for those not connected with the Institute will be issued up to July 27th at the offices of the Institute, or at the offices of the local treasurer at the City Treasurer's Office, Guildhall, Hull, and on the following days at the Reception Room in the School of Art. Ladies' tickets (not including copies of the proceedings) 10s. 6d. each. Lists of hotel and boarding-house accommodation may be obtained on application to the secretaries.

Notes, Comments, and Abstracts.

TYPHUS FEVER EPIDEMIC AMONG THE GREEK REFUGEES.

By Sir Patrick Hehir, K.C.I.E., C.B., C.M.G., M.D. Brux., F.R.C.S., F.R.C.P. Edin.,

MAJOR-GENERAL, I.M.S. (RET.); MEDICAL ADVISER, BRITISH RED CROSS SOCIETY IN GREECE.

It has fallen to my lot to see a great deal of typhus among the Greek refugees during the last four and a half months. As the outbreak presents many points of difference, epidemiologically and otherwise, from the disease as ordinarily met with elsewhere, an account of it may be of interest. The Greek refugees primarily brought the infection with them, and have been moving from one place to another carrying the disease, either in the incubating stage or in a mild ambulatory form. The serious cases are, of course, incapable of movement with the masses.

Epidemiology.

The epidemiological history of the present outbreak is easily understood if one pictures the conditions, economic, political, and military, that have been in existence in relation to these refugees since last autumn. Apparently there is a gradual rise in the intensity of the epidemic until it reaches its acme; this continues for a few months and then the epidemic gradually subsides. There are, however, oscillations in the intensity which, I believe, are mainly associated with variations in meteorological conditions, but doubtless other accidental factors are concerned. With us it began at the end of January, gradually rose in numbers and severity of attacks, reached a maximum about the first fortnight in March, remained stationary for a month or so, and is now undergoing a marked abatement.

It is noteworthy that in areas where refugees have been widely dispersed on the land there has been no typhus, or it has not become epidemic when introduced. Other things being equal, the intensity of the epidemic appears to depend largely upon the economic conditions in existence. The relation of typhus to overcrowding, long misunderstood, is now known to be easily explained by the part that human lice play in the disease. The brunt of the epidemic has been borne by the larger towns—e.g., Athens and its environs, Salonica, Patras, Corfu—the smaller towns escaping to a considerable extent, the incidence being related to the density of population on the occupied area. Whole rural districts in Macedonia and Western Thrace have escaped altogether. The housing conditions of the refugees, their hardships—especially insufficient food and exposure—have considerably lowered their resistance to disease, which, except in the case of minor maladies, runs a serious course and is frequently fatal. This high mortality is important, as it has aroused antipathy to the hospitals; early cases of sickness are hidden, and often hospital relief is only sought when the patient is dangerously ill, this being one of the ways in which typhus is being spread.

The outbreak attained its maximum of intensity in mid-winter. In colder weather the people are more crowded together; they wear thicker clothes, which foster lice, and bathe less frequently. Throughout the winter refugees were packed with the ordinary civil population in the waiting rooms of railway stations and in other places; contact cases were therefore more frequent. As I write this in the British Red Cross train at Salonica railway station, a refugee-train is in a siding; in and around the station yard are, roughly, 500 refugees, all on the way to Seres (Thrace) to take up work on the land. The same sort of arrivals and distributions are occurring in many large railway stations; it is easy to see how communicable disease spreads rapidly among them, and also reaches the stationary populations of towns.

Overcrowding is, however, only one of the factors that enter into the epidemiology of typhus. Other hardships exist: A very large percentage of the refugees get only a bare subsistence allowance of food. In some districts men who can work get no food dole, and out-of-work women get only 6 to 8 ounces of bread or flour a day. Until a few months ago few refugees had a change of clothing; undergarments were especially scarce. A great deal of help has been given them now in this respect, and I know of no camp of any duration that has not been relieved. With only one suit of clothes the practical difficulties of delousing are obvious; the suit is put through the steam disinfector and dried while the refugee is having his bath. The sanitary condition under which refugees lived for months after their return to Greece was indescribably bad; it has, in the last two months or so, been greatly ameliorated.

It is superfluous to state that the infected human louse is the intermediary in the transmission of typhus; ordinarily there is no direct communication of the disease from man to man. If it were possible to exterminate human lice in an infected area the disease would cease. All our radical preventive measures are based on this knowledge. Experienced local medical administrators act on the principle that if there are no lice on the people themselves and their clothes they cannot give the disease to others. Somehow it has got abroad that it is only the body-louse that acts as a carrier. I am all but morally certain that this is not the case, and that the exculpation of *P. capitis* is a dangerous theory.

The micro-organism of typhus passes through a developmental stage in the louse; in that insect it is intracellular, develops, is set free, and is finally discharged into the oral apparatus, from which it is introduced into man. In man it again becomes intracellular, and from the infected cells it is thrown into the blood with its toxins. The louse does not transmit the virus until four days have elapsed from the time of its infection; infection of man is in the vast majority of cases through the bite of the louse, and the insect's excreta rubbed into scratches of the skin is also believed to give rise to infection in a small number of cases. So far as I can discover, no original work is being done during this epidemic in regard to the relation of the louse to typhus.

The infectious diseases hospitals for typhus cases in refugees are not ideal institutions, but they might be worse. There is usually a sufficient number of sick attendants, nurses, and doctors, but want of experience as to how to deal with the disease has been evident in several local epidemics. The arrangements for protecting the hospital staff from infected lice was one of the most serious defects I came across. When I visited an infectious diseases hospital some weeks ago a long white coat was given me to wear in the wards. After I had put it on one of the hospital orderlies picked off a louse from the neck, remarking that it was seldom he found one on the assistant director's gown which I was wearing. In one infectious diseases hospital the arrangements for delousing patients admitted were of the most elementary kind, except that a steam-disinfector was occasionally used for the clothing when water was available. There was no bathing of patients on admission, but the hair was cut short. I found that the sanitary arrangements in wards and latrines called for serious improvement—some of the wards were offensive, as several cases of incontinence of urine and fæces were present and the nursing and cleanliness were unsatisfactory. In our own camp one day I found that three cases which the Greek medical officer (himself a refugee) had diagnosed as "fever" had been allowed to remain in the main blocks. All three had lice on their clothes; they were all cases of typhus and two of them already had the rash. In one town a severe epidemic of influenza was reported to exist, but the high mortality aroused suspicion and inquiries by experts were made; it was found that influenza was the minor disease and typhus the real epidemic. The same history was given me by the controlling medical authority in regard to two other towns. As the result of this want of experience several doctors and nurses taking no precautions got the disease and died. It is all but morally certain that anyone attending typhus cases without a knowledge of the nature of the disease will become infected himself sooner or later. It is important to educate the subordinate staff of these hospitals in the ætiology of typhus and the principles adopted in the prevention of infection.

(*To be continued.*)

MEDICAL WORK OF THE MISSION TO LEPERS.

The forty-eighth annual report of the Mission to Lepers,[1] presented at the annual general meeting of members of the mission at the Central Hall, Westminster, on May 10th, contains a chapter devoted to the medical work of the mission, in which short statements by various medical men and women are quoted. The mission cares for 7735 leper inmates in its own and aided institutions, and also for over 600 untainted children, who are educated and trained in separate homes to become useful members of the healthy community. At Dichpalli, near Nizamabad, Deccan, India, improved results have been obtained by intravenous injection of the ethyl esters of chaulmoogra or hydnocarpus oils, as opposed to intramuscular injection. "This means that very much more of the drug is administered, with consequent signs of improvement. In nodular cases an auto-vaccine is prepared for each patient." In some cases the two methods are combined. The conditions of unrest in China militate against the handling of the leper problem: "In Siao Kan (Central China), since the middle of the war period, we have only encouraged the more pronounced, or chronic, cases to come into residence. This means that we have turned away the very cases which the treatment would have best served, for undeniably the esters act most rapidly in the early stages of the disease." From the Fusan Leper Asylum, Korea, the honorary superintendent writes: "Before we began the chaulmoogra oil treatment our death-rate was always as high as 25 per cent. The inmates had little or no hope of a cure; . . . it was with the greatest difficulty that they could be got to do any kind of work. Now, with the exception of those who are maimed or blind. . . . they form a hive of industry and are as happy a crowd as one can see anywhere. We have already discharged nine cases in which no trace of the disease could be found; and there are, perhaps, double that number who have no active symptoms though they still have some anæsthetic patches. . . . In the first year of the treatment the death-rate was reduced from 25 to 15 per cent., though only about half the patients were given the injections. Since then the percentage in successive years came down to 9, 6, 6, 5, 4, and for the past year it stands at 2½ per cent.; but as half the deaths resulted from an epidemic of typhoid, it may be said that the death-rate from normal causes was only 1¼ per cent. This is specially remarkable when it is remembered that only cases far on in the disease have been admitted for several years. These results are from Dr. Wilson's method of intramuscular injections of whole chaulmoogra oil, camphorated. The new Dean treatment with ethyl esters of chaulmoogra oil gives promise of still better results." In a short article appended to the report Dr. E. Muir, leprosy research worker in the School of Tropical Medicine, Calcutta, states that the most hopeful feature in connexion with leprosy in India is the increasing interest being taken in the problem by the medical profession and the public alike. The leper beggars in the streets have, he remarks, generally reached a stage at which the lepra bacillus has died out of the system; although there is danger from this source, the chief danger is from those who mix in various grades of society, from the highest downward, who are either unaware of, or are concealing, the fact that they are disseminating the disease. Dr. Muir has "come across cooks and house-servants, schoolboys attending school, students attending college, teachers of both sexes instructing the young, confectioners serving over the counter, and men and women in other walks of life, all in a position to spread the disease to those around them."

A NEW GAS-MASK.

CONSIDERABLE study has been devoted since the war to gas warfare in the United States, and the Bureau of Mines of Pittsburg in Pennsylvania has in consequence developed a "universal gas-mask,"[1] which, with its harness, weighs 8½ lb., and protects, though for a short time only, against small doses of most noxious gases. It produces no oxygen, so cannot serve as a protection in atmospheres deprived of oxygen, and no atmosphere which extinguishes a candle can be entered with reliance on this mask; a self-contained oxygen-breathing apparatus must then be used. In this "universal gas-mask" the entering air first passes through (*a*) an activated charcoal, to remove organic vapours, then through (*b*) a filter of cotton-wool to remove smokes, dusts, and mists; next comes (*c*) caustic soda, fused on pumice stone, to remove acid gases. These are followed by (*d*) another cotton-wool filter; (*e*) fused calcium chloride, to extract water vapour which would inhibit the action of the next absorbent; (*f*) "hopcalite," a mixture of oxides of manganese and copper, with sometimes silver and cobalt, to destroy carbon monoxide; and finally (*g*) silica gel for absorbing ammonia. This mask is considered to be safe for six hours of use. It has been used for 14 hours, but not without great risk, for when carbonic oxide absorption is completed and that gas is coming through no warning is given. How thirsty the wearer must have been after inspiring air all that time through fused calcium chloride, and in the dry atmosphere of the United States, too! A smaller equipment for firemen weighs 5½ lb., and gives protection for four hours.

THE TRAINED CLIMBER.

MANY medical men know the value of Swiss mountain air for holidays after heavy work; some make a point of spending a month every year there. For the strenuous mountain-climbing is an attraction, and it is of interest to learn that for the timid amateur who dreads being a drag on other climbers a scientific course of instruction, theoretical and practical, in mountaineering will be given at the end of July in the beautiful village of Klosters, in the Grisons district, at a fee of £6 6s., including board. Full particulars may be had from Gustav Walty, Klosters.

Of importance in this connexion is an article on Muscular Exercise by Prof. A. V. Hill, F.R.S., in *Nature* of July 14th, in which recent work on muscle contraction and recovery is summarised, leading to the modern view that man's power of taking exercise, whether violent or prolonged, depends largely on his ability to run into debt for oxygen. In prolonged effort, such as that associated with climbing, the healthy man is limited not by the magnitude of "debt" into which his body can run—not, that is to say, by the lactic acid maximum of his muscles—but chiefly by the maximum rate at which he can take in oxygen. With regard to the economical use of muscle by the trained athlete, Prof. Hill writes as follows:—

"Clearly if a given movement can be carried out more economically—i.e., at the expense of less energy—then less oxygen will be required for it, and its maximum duration can be increased. . . . This economy of effort can, in part, be taught; but just as all the practice in the world will not turn some quite intelligent people into mathematicians, so all the practice in the world may never turn some quite powerful and well-developed people into first-class athletes. Training and practice are essential, but they can only build on an aptitude already there. If a subject uses his muscles uneconomically . . . he will need an excessive supply of oxygen. Consequently he will be an ineffective athlete . . . he is uneconomical. Athletic prowess depends not only upon a large oxygen supply, but upon a low oxygen requirement."

Skill, power, and economy of muscular effort result, Prof. Hill says, from the effectiveness of the "quick, silent, overmastering, and generally unconscious reactions, dictated by the nervous system on the receipt of urgent messages from tendons, joints, and muscles, or from the little sense organs associated with the ear. . . . The instinctive skill, quickness, and economy of the gymnast or climber, of the mechanic, airman, tennis-player, or athlete, depend upon a vivid and readily reproducible picture in the brain or nervous system, 'a picture,' as Pear puts it, 'of muscular exercise in terms of the sensations which effective and successful movements produce.'"

These considerations are very pertinent to the climbing course at Klosters, and a timely study of them by the would-be climber might save him disappointment.

THE DRIVING GRIP IN GOLF.

To the Editor of THE LANCET.

SIR,—Professional golfers should be grateful to Dr. Wm. Cuthbert Morton for the scientific confirmation in your issue of June 30th of the fact long appreciated by professionals, but difficult to convey to pupils, that the golf club must be held with the wrist slightly extended, "especially the left one," if full power is to be exerted in the grip. Can you explain why this should be? I find golf pupils are much more ready to obey instruction when a logical explanation of the reason for a position can be given. The slanting grip of the fingers with extended wrist seems unnatural and uncomfortable to most beginners.

One further point which Dr. Morton does not elaborate is the general impression among professionals that the grip is principally maintained by the forefinger and thumb of both hands. The real gripping power is, of course, in the flexion of the middle, ring, and little fingers, whereas the strain felt between or with the first finger and thumb is due to the sharp contraction of the first interosseous muscle which approximates finger and thumb to prevent the handle of the club from dropping into the groove or web between them. I am, Sir, yours faithfully,

DAVID ANDERSON.

York Gate, Regent's Park, July 12th, 1923.

PROFESSIONAL CLASSES AID COUNCIL.

THE Professional Classes Aid Council, reconstituted in April, 1921, to carry on and extend the work arising out of the Professional Classes War Relief Council, has now completed its second year of work. The council exists to relieve, or assist in relieving, distress among the professional and other highly educated classes and their dependents, and that work has been steadily consolidated during the past 12 months. As a general rule the council does not give financial assistance to persons suffering from misfortune which could have been naturally foreseen and reasonably provided against, although in such cases helpful advice can frequently be offered. The aim in giving financial assistance is to enable the recipient to become independent of further help. Doctors, nurses, and medical students were among those helped directly and indirectly during 1922, the council of the association being careful to avoid usurping the functions of existing benevolent funds. The direct relief given is at present severely limited by want of funds. The hon. treasurer of the association (of which Sir Clifford Allbutt is a patron and Dr. G. Newton Pitt, representing the Royal Medical Benevolent Fund, a member of the council) is Mr. E. W. Monkhouse, and the offices are at 251, Brompton-road, London, S.W. 3.

An Address

[ABRIDGED]

ON

ENVIRONMENT AND HEALTH.

Being the Presidential Address delivered at the Annual Meeting of the British Medical Association in Portsmouth on July 24th, 1923,

By CHARLES P. CHILDE, F.R.C.S. Eng., M.R.C.P. Edin.,

SENIOR SURGEON, ROYAL PORTSMOUTH HOSPITAL.

[After welcoming the members of the Association and calling attention to the previous meeting held at Portsmouth in 1899, Mr. Childe commented on the past history and present development of the town. He proceeded :—]

During the past fifty years medicine has done infinitely more to constitute itself a science than in all the previous ages. This has been mainly due to the flood of light thrown upon the specific ætiology of many diseases by the epoch-making discoveries of Pasteur, and the stimulus those discoveries have given to other workers. Previous to this almost nothing was known of the agencies concerned in the onset of any diseases, except those of purely mechanical origin. Of such widespread and prevalent disorders as the surgical infections, enteric fever, tuberculosis, diphtheria, syphilis, malarial fever, pneumonia, and many others, the causes were entirely unknown, the speculations and theories as to their origins were various—" Quot homines, tot sententiæ "—and their treatment was entirely empirical. All disease was a mystery. A great deal of it is no longer a mystery. Approximately one-half of the diseases with which we are acquainted are now known to have their origin in infection by living organisms belonging either to the plant or to the animal kingdom, and the probability is that the list is not yet nearly exhausted. Besides this, it has been computed that nearly half the deaths that occur annually are traceable to the same cause.

With the emergence of medicine from the mysterious no less a revolution has occurred in the practitioner of medicine. While a good bedside manner is still a valuable asset, and will so remain in so far as it connotes a sympathetic and human attitude towards the sick and suffering, and while from a business point of view a good shop-front no doubt has its value, no longer are the doctor's brains assessed by the sheen of his tall hat or the length of his frock-coat. Like medicine, the doctor has become less mysterious, less aloof from and superior to his fellow men. Knowing more he has become less omniscient. Standing on surer ground he has become less pretentious. The medical priestcraft, reminiscent of a time when the medicine-man was more priest than physician, and more charlatan than either, has disappeared or is disappearing. This is all to the good, and tends to a more enlightened confidence between doctor and patient.

Again, so much relating to the discoveries and advances in medicine nowadays finds its way into the lay press that the general public has, apart from its technical aspects, a broad knowledge of the progress medicine is making, and is alive to its new developments. This is again to the good. A strong opposition is always an incentive to good government. The advent of a wideawake and informed public tends to keep the profession up to the mark. It adds nothing to the dignity, not to mention the security, of the doctor to be questioned by his patient on some new treatment or phase of a disease he has never heard of, but with which he finds his patient has more than a bowing acquaintance.

It was a natural sequence of the elucidation of the causative agent in many of the infectious diseases that scientific effort should be directed to two main objectives: first, to the discovery of means of producing an artificial immunity similar to the active natural immunity which it was a matter of common knowledge resulted after recovery from an attack of many of them; secondly, to producing immunity reactions which should have the effect of neutralising the toxic products of the invading organisms during an attack. In both of these directions remarkable results have been achieved, both by what is known as vaccine prophylaxis and therapy, and antiserum prophylaxis and therapy.

Successes in Prophylaxis.

The most completely successful example of *vaccine prophylaxis* is that of vaccination against small-pox, introduced by Jenner in 1798. This remarkable discovery was the result of shrewd observation and logical deduction. It was, nevertheless, empirical; the principle on which it rested was not understood until the work of Pasteur more than half a century later. In countries where vaccination is twice practised, small-pox has practically ceased to exist, and its sporadic outbreak from time to time is a warning to the public of neglect of the means to prevent it. In typhoid and paratyphoid fever, by measures along the same lines, immunity lasting for a period of one or two years can be secured, and has greatly reduced the incidence of these diseases both among civilians and soldiers.

Again, the mortality from rabies has been reduced from 16 per cent. to a fraction of 1 per cent., an active immunity being capable of being produced here after infection has already taken place, owing to the lengthy incubation period of the disease. *Vaccine therapy*—that is, the production of active immunity after attack by a known micro-organism—so ably advocated by our own countryman, Sir Almroth Wright, has given very beneficial results in staphylococcus infections, skin affections, &c. Of *antiserum prophylaxis* the best example is that obtained in tetanus. The mortality following Fourth of July injuries in America has ceased to exist owing to its use, and no less life-saving results were obtained by the same means in the Great War. The most familiar and the most successful instance of *antiserum therapy* is that of diphtheria, which has reduced the mortality from 40 to 10 per cent., and, if used on the first day of the disease, to almost *nil*.

These are veritable triumphs of strictly scientific medicine. In other diseases more or less success has been achieved. But closer investigation has shown that there are many factors requiring elucidation which undoubtedly influence the result—such as choice of route, recognition of different types of the same disease, &c.—and it will certainly take many years of patient endeavour before the ultimate possible results in securing immunity are obtained. In many instances prophylaxis or cure has eluded us, and the results have proved disappointing. The above may be termed the result of scientific effort, either preventive or curative, directed towards the individual.

There are other diseases, which have been attacked from a totally different angle—namely, by studying and combating conditions which favour the growth, dissemination, and virulence of the infecting organism, by so altering environment and increasing natural resistance, whatever that may precisely mean, that many diseases which have been very prevalent and very fatal in the past have almost or entirely ceased to exist, and are no longer of any account. Let me give you one or two very familiar examples.

Take typhus fever. During the last century it prevailed in all the large cities of Great Britain and the Continent. So late as 1875 in England and Wales there were 1499 deaths from the disease. During recent years the name " typhus " has seldom appeared in the Registrar-General's returns. It is a disease essentially dependent on filth and overcrowding. Bad as these conditions are even now in our large industrial centres, the disappearance of this disease is evidence of an improvement as compared with half a century ago—an improvement in environment and an improvement in natural resistance, owing to better living conditions, sufficient to have caused its disappearance altogether.

5213

After the peace of 1815, following a long and exhausting war, when the economic position was somewhat similar to that existing at the present time, typhus fever and relapsing fever, which occurs under similar conditions to typhus, were rife in England and Ireland. No such catastrophe has accompanied the economic depression following the last Great War.

Take, again, typhoid fever. It is a water-borne disease. Bad drainage and a contaminated water-supply are the factors favouring its distribution. Its prevalence or the reverse in a community is the measure of their sanitary intelligence and enterprise. Filth, overcrowding, and bad ventilation are factors conducing to its prevalence, by lowering natural resistance. The marked decline in typhoid fever is again the result of an improvement in environment. Typhoid fever has declined from 375 per million in 1870 to 25 per million at the present time. In Portsmouth typhoid fever, quite prevalent in the town when I came here 30 years ago, has almost ceased to exist.

These are examples of diseases which have disappeared, or are disappearing, owing to action following an intelligent study and comprehension of the conditions and environment favouring their distribution.

Now, "environment" is obviously a very wide term. It embraces living conditions generally. The amount and quality of food and water, the presence or absence of domestic hygiene, the supply or not of good drainage, the furnishing or not of healthy conditions in factory and workshop, the prevalence or not of smoke and fog, the provision or not of adequate open spaces, playgrounds, and recreation grounds, access or not to sound education—these and many others are all factors in environment. And it is satisfactory to note that these matters are receiving from governments and local authorities some of the attention which all of them deserve. But I propose to-night to consider for a few moments the special environmental factors governing the slum areas of our great industrial centres—the lack of fresh air and sunlight, and the cramped and penalising conditions to health, both moral and physical, owing to overcrowding; and to inquire what bearing these factors have upon four out of five of the most formidable endemic scourges which afflict all northern civilised peoples to-day.

THE BEARING OF ENVIRONMENTAL FACTORS ON DIFFERENT DISEASES.

The five scourges I allude to are cancer, tuberculosis, rickets, venereal disease, and alcoholism. Tuberculosis and rickets account for most of the cripples we see about us; cancer, tuberculosis, venereal disease, and alcoholism account for most of the deaths; venereal disease and alcoholism account for most of the misery and moral degradation of our race.

Cancer.

We may dismiss cancer at once from the count. The humiliating confession must be made that we know very little about it. That it has some relation to civilised environment seems evident from the fact that it is a comparatively rare disease among primitive races, and that it is certainly making rapid headway among all civilised peoples. But of the nature of the environment favouring its activities we are in complete ignorance. It is neither foul air nor fresh air, neither hardship nor indulgence, neither poverty nor riches. Cancer like death—

"Æquo pulsat pede pauperum tabernas,
Regumque turres."

The only things we know about it which are worth knowing are its age-incidence, its relation to chronic irritation, and the fact that it is in its beginnings a local disease, and that therefore it can be cured by early removal in those situations where removal is possible.

This is practically all we know about cancer. I wish to make only two comments. The first is that this knowledge is not enough. In an age which has yielded secrets of so many diseases it is a point of honour with the medical profession not to rest content till this pressing problem has been solved. With the public it is not only an obligation but, from the point of view of their own interest and safety, a vital necessity to furnish the financial means of solution, and to see to it that research is not crippled or stinted by any niggardly parsimony.

The second comment I make is this: The most important fact we know about the disease is that in its beginnings it is local, and that its course is a centrifugal spread from its local point of origin. Is that knowledge anything like as productive as it might be? Undoubtedly it is not. Notwithstanding the fact that cancer has been cured over and over again by modern operation—a fact which in itself proves that it is curable—yet I believe patients come no earlier to the doctor with it than they did 30 years ago, though time is the very condition of the only cure we possess for it. Many medical men, and I confess I am one of them, are of opinion that there is considerable room for improvement in this direction. Without resort to any sensationalism some obvious steps could be taken to spread the knowledge of a few very simple facts about cancer. This would give a by no means unwarranted ray of hope to the public and would enable some of the victims of this terrible disease to apply in time to have, at all events, a chance of cure or freedom from recurrence, whichever you like to call it. This by the way.

I pass on to the consideration of the other four scourges—tuberculosis, rickets, venereal disease, and alcoholism.

Tuberculosis.

Tuberculosis first. We know the cause; it is the tubercle bacillus. We know also the prime and essential conditions of its cure; they are fresh air and sunlight. These are not only the essential conditions of its cure, but are almost the sole conditions. Those of you who are interested in the subject will have an opportunity of visiting the establishments at Alton and Hayling Island, under the able administration of Sir Henry Gauvain, where the cures are fresh air and sunlight. Dr. A. Rollier, of Leysin, read a most instructive paper at the Glasgow meeting last year, and quoted many instances of cures, and lasting cures, by these agencies in all regions of the body. It is foreign to my purpose to discuss to-night the method or supposed method of their action, or the method of their application. If, then, these agencies, fresh air and sunlight, are, as we know they are, so powerfully antagonistic to tuberculosis—whether by directly controlling the activities and virulence of the tubercle bacillus itself or by fortifying the natural resistance and so enabling the human organism to establish an immunity to it (it matters not, the result is the same)—are we not justified in the converse conclusion, that the breeding ground of this disease, the environment most encouraging to its activities, are the sunless, airless, overcrowded, and insanitary slum areas of our great cities, where houses are built 40 or more to the acre, and stand back to back, and side to side, like any jig-saw puzzle, so that fresh air and sunlight, the proved destructive agents of the tubercle bacillus, can never enter? Is it a sound economic proposition to equip and maintain, at the cost of millions of the taxpayer's money, sanatoriums for the so-called cure of tuberculosis, while we guard intact the very preserves of this disease by the exclusion of fresh air and sunlight, which cost nothing at all, and maintain in our midst a soil which can breed more tuberculosis in a week than all our sanatoriums can cure in a year? Dr. Rollier says:—

> "Housing has played an immense part in the genesis of child and adult tuberculosis; the community bears the responsibility of the waste of human lives through insanitary houses."

The industrialisation of Sweden since 1870 has been accompanied by a high adolescent mortality due to pulmonary tuberculosis. Sandberg, commenting on this, says:—

> "The cause of this difference between earlier and more recent times seems to us to be in the fact that formerly the adolescent boy and girl remained at home for a longer time —nowadays one goes more frequently and at an earlier age

to the city or factory. The new conditions of existence bring, in many cases, increased dangers to health and life, dangers which, especially in the case of women, often lead to tuberculosis."

In 1885 the tuberculosis gland cases admitted to the Alexandra Hospital for Sick Children, Brighton, constituted 6·5 per cent. of all admissions. In 1899 they were 3·5 per cent.—a reduction of nearly 50 per cent. Between 1885 and 1899 Brighton has swept away most of its insanitary areas. Numbers of similar instances could be quoted. It is no unwarrantable assumption that by permitting—and that is all we have to do—the sun and fresh air into our slum areas we should see a very marked general decline in the incidence of tuberculosis.

Rickets.

Consider next rickets. Its ætiology is unknown. There are two opposing theories as to its origin—the dietetic and the hygienic. There are those who positively assert that it is a deficiency disease; that it is due mainly to lack of fat-soluble A. There are others who as stoutly deny that diet has anything to do with it. We may leave the theorists to settle their differences and turn our attention to certain facts about it which have long been established, and certain other facts which have recently come to light. It never occurs among races living under natural conditions, and is especially prevalent among the poor in Europe and America living under so-called civilised industrial conditions—in other words, the thoroughly bad hygienic conditions of overcrowding and absence of fresh air and sunlight. Among the well-to-do it is practically unknown. In India, on the other hand, as recently shown by Hutchinson, it is a disease of the rich. It does not occur among the poor labouring class who live an open-air life, but is prevalent among the rich Mohammedans and Hindus, who are confined in airless and sunless rooms. Hutchinson discovered also this remarkable fact—that late rickets was restricted to females, who alone are confined, according to the purdah system of isolation as practised by the wealthy natives of India. Again, eminent observers in Glasgow, who have quite an exceptional acquaintance with rickets—it being, as you know, very prevalent in that city—have always associated the disease with overcrowding and lack of hygienic conditions and sunshine, which you also know are conspicuous features of that great hive of industry. According to Miss Fergusson, 50 per cent. of the children in the poor quarters of Glasgow are rickety—a vastly smaller proportion in garden cities, such as Bournville. The prevalence of rickets, she says, is associated with close confinement in tenements. Most important of all, we have the recent experiments of the Lister Institute in Vienna. They prove conclusively that a deficient diet can only produce rickets in the absence of sunlight. If abundant sunlight be present a deficient diet is powerless to give rise to it. Lastly, we have the significant fact that the sun's rays without any other treatment whatever can cure it—an explanation of the oft-repeated dictum that anybody can cure rickets in the summer.

All this does not prove that the absence of fresh air and sunlight is the cause of rickets; but it does prove this—that in overcrowding, confinement, want of fresh air and sunlight, we have an environment conducive to the development of rickets, either by the supply of conditions favourable to the activities of the virus, whether microbic or otherwise, or by lowering natural resistance to it. Conversely, that fresh air and sunlight and good hygienic conditions furnish an environment which is powerfully antagonistic to the disease; that they have either the power of damping down the activities of the virus whatever it is, or that they can so alter the metabolism of the body as to provide an increased resistance and immunity to it. Whichever is the method, the result is the same. These facts appear to indicate clearly and unmistakably the way to the control of this crippling and dangerous disease. And, as Mellanby says, its eradication would do away with a great deal of the bone deformity, improve the physique, lower the infantile mortality, and, most important of all, improve the teeth of the people of this country beyond recognition.

Venereal Diseases.

Let me invite your attention in the next place to venereal diseases, which have figured so largely in the public eye during recent years, are discussed in every drawing-room, exhibited at every picture-house, and with regard to the most suitable methods of controlling which there are acute differences of opinion, both among medical men and the lay public. They are the diseases of immorality. The contributing environmental factor here is the indiscriminate admixture of the sexes of all ages, a necessity of their living conditions. It is not, of course, contended that by an improvement in housing immorality would be stamped out, but it is contended that the conditions of overcrowding, without regard to age or sex, which exist in our industrial centres make the practice of morality wellnigh impossible.

Let me put before you a few facts; they are taken from the report of Dr. A. K. Chalmers, the medical officer of health for Glasgow, for 1921. There is no intention to single out that city as a sink of iniquity, or an example of a condition of things peculiarly revolting to the conscience of civilised humanity, and I have very little doubt its case could be paralleled in our own borough of Portsmouth; but I have the facts for Glasgow, and I have not similar facts for Portsmouth. In Glasgow, out of a population exceeding a million, over 600,000 live in one-roomed or two-roomed tenements. Under the heading "Sex overcrowding in small houses," Dr. Chalmers gives the following appalling examples:—

> "In a one-roomed house a father of 52 occupied the same bed with a mentally defective daughter of 24, who had an illegitimate child of 10. In another, with space for five adults, a father and daughter shared the same bed. In another a mother shared the same bed with two sons of 19 and 20 years respectively. In two-roomed houses, in one instance a son of 19 and a daughter of 21 occupied the same bed; and in another a son of 19 and a daughter of 25, who was pregnant."

However revolting these facts may be, it is right that the public should be made aware of them. This, then, being an example of the state of affairs in our industrial centres, it may be confidently stated that a great deal, at all events, of immorality and its consequences, venereal disease, is the direct result of environment—that the conditions existing make either the teaching or practice of morality impossible, and furnish the breeding ground for venereal disease.

Have we not, it may be asked, missed one phase of the problem, and are we not somewhat out of touch with the situation, with our societies for the prevention of venereal disease and for combating venereal disease quarrelling amongst themselves as to the best means of meeting the evil, and local authorities and the lay public equally divided, when conditions such as I have depicted are rampant in our midst? It is this aspect of the problem—the immorality and its consequence, venereal disease, which are the direct result of overcrowding without regard to age or sex—which I wish to lay particular stress upon here.

The Abuse of Alcohol.

Consider, lastly, the abuse of alcohol. There is no doubt that, without anything in the nature of prohibition in this country (and I believe it to be foreign to the instincts of our people to have their lives, what they may eat, and what they may drink, regulated by the policeman), there has taken place during the past 50 years a steady move in the direction of greater sobriety among all classes of the community. Among the upper and middle classes drunkenness was the fashion less than a century ago. It is now a disgrace. In the army, navy, and mercantile marine there was, 50 years ago, infinitely more drinking than there is to-day. In the streets of our towns the drunken man of any class is not nearly such a familiar sight as he was a generation ago. This must be attributed broa

After the peace of 1815, following a long and exhausting war, when the economic position was somewhat similar to that existing at the present time, typhus fever and relapsing fever, which occurs under similar conditions to typhus, were rife in England and Ireland. No such catastrophe has accompanied the economic depression following the last Great War.

Take, again, typhoid fever. It is a water-borne disease. Bad drainage and a contaminated water-supply are the factors favouring its distribution. Its prevalence or the reverse in a community is the measure of their sanitary intelligence and enterprise. Filth, overcrowding, and bad ventilation are factors conducing to its prevalence, by lowering natural resistance. The marked decline in typhoid fever is again the result of an improvement in environment. Typhoid fever has declined from 375 per million in 1870 to 25 per million at the present time. In Portsmouth typhoid fever, quite prevalent in the town when I came here 30 years ago, has almost ceased to exist.

These are examples of diseases which have disappeared, or are disappearing, owing to action following an intelligent study and comprehension of the conditions and environment favouring their distribution.

Now, "environment" is obviously a very wide term. It embraces living conditions generally. The amount and quality of food and water, the presence or absence of domestic hygiene, the supply or not of good drainage, the furnishing or not of healthy conditions in factory and workshop, the prevalence or not of smoke and fog, the provision or not of adequate open spaces, playgrounds, and recreation grounds, access or not to sound education—these and many others are all factors in environment. And it is satisfactory to note that these matters are receiving from governments and local authorities some of the attention which all of them deserve. But I propose to-night to consider for a few moments the special environmental factors governing the slum areas of our great industrial centres—the lack of fresh air and sunlight, and the cramped and penalising conditions to health, both moral and physical, owing to overcrowding; and to inquire what bearing these factors have upon four out of five of the most formidable endemic scourges which afflict all northern civilised peoples to-day.

THE BEARING OF ENVIRONMENTAL FACTORS ON DIFFERENT DISEASES.

The five scourges I allude to are cancer, tuberculosis, rickets, venereal disease, and alcoholism. Tuberculosis and rickets account for most of the cripples we see about us; cancer, tuberculosis, venereal disease, and alcoholism account for most of the deaths; venereal disease and alcoholism account for most of the misery and moral degradation of our race.

Cancer.

We may dismiss cancer at once from the count. The humiliating confession must be made that we know very little about it. That it has some relation to civilised environment seems evident from the fact that it is a comparatively rare disease among primitive races, and that it is certainly making rapid headway among all civilised peoples. But of the nature of the environment favouring its activities we are in complete ignorance. It is neither foul air nor fresh air, neither hardship nor indulgence, neither poverty nor riches. Cancer like death—

"Æquo pulsat pede pauperum tabernas,
Regumque turres."

The only things we know about it which are worth knowing are its age-incidence, its relation to chronic irritation, and the fact that it is in its beginnings a local disease, and that therefore it can be cured by early removal in those situations where removal is possible.

This is practically all we know about cancer. I wish to make only two comments. The first is that this knowledge is not enough. In an age which has yielded secrets of so many diseases it is a point of honour with the medical profession not to rest content till this pressing problem has been solved. With the public it is not only an obligation but, from the point of view of their own interest and safety, a vital necessity to furnish the financial means of solution, and to see to it that research is not crippled or stinted by any niggardly parsimony.

The second comment I make is this: The most important fact we know about the disease is that in its beginnings it is local, and that its course is a centrifugal spread from its local point of origin. Is that knowledge anything like as productive as it might be? Undoubtedly it is not. Notwithstanding the fact that cancer has been cured over and over again by modern operation—a fact which in itself proves that it is curable—yet I believe patients come no earlier to the doctor with it than they did 30 years ago, though time is the very condition of the only cure we possess for it. Many medical men, and I confess I am one of them, are of opinion that there is considerable room for improvement in this direction. Without resort to any sensationalism some obvious steps could be taken to spread the knowledge of a few very simple facts about cancer. This would give a by no means unwarranted ray of hope to the public and would enable some of the victims of this terrible disease to apply in time to have, at all events, a chance of cure or freedom from recurrence, whichever you like to call it. This by the way.

I pass on to the consideration of the other four scourges—tuberculosis, rickets, venereal disease, and alcoholism.

Tuberculosis.

Tuberculosis first. We know the cause; it is the tubercle bacillus. We know also the prime and essential conditions of its cure; they are fresh air and sunlight. These are not only the essential conditions of its cure, but are almost the sole conditions. Those of you who are interested in the subject will have an opportunity of visiting the establishments at Alton and Hayling Island, under the able administration of Sir Henry Gauvain, where the cures are fresh air and sunlight. Dr. A. Rollier, of Leysin, read a most instructive paper at the Glasgow meeting last year, and quoted many instances of cures, and lasting cures, by these agencies in all regions of the body. It is foreign to my purpose to discuss to-night the method or supposed method of their action, or the method of their application. Is it a sound economic proposition to equip and maintain, at the cost of millions of the taxpayer's money, sanatoriums for the so-called cure of tuberculosis, while we guard intact the very preserves of this disease by the exclusion of fresh air and sunlight, which cost nothing at all, and maintain in our midst a soil which can breed more tuberculosis in a week than all our sanatoriums can cure in a year? Dr. Rollier says:—

> "Housing has played an immense part in the genesis of child and adult tuberculosis; the community bears the responsibility of the waste of human lives through insanitary houses."

The industrialisation of Sweden since 1870 has been accompanied by a high adolescent mortality due to pulmonary tuberculosis. Sandberg, commenting on this, says:—

> "The cause of this difference between earlier and more recent times seems to us to be in the fact that formerly the adolescent boy and girl remained at home for a longer time—nowadays one goes more frequently and at an earlier age

to the city or factory. The new conditions of existence bring, in many cases, increased dangers to health and life, dangers which, especially in the case of women, often lead to tuberculosis."

In 1885 the tuberculosis gland cases admitted to the Alexandra Hospital for Sick Children, Brighton, constituted 6·5 per cent. of all admissions. In 1899 they were 3·5 per cent.—a reduction of nearly 50 per cent. Between 1885 and 1899 Brighton has swept away most of its insanitary areas. Numbers of similar instances could be quoted. It is no unwarrantable assumption that by permitting—and that is all we have to do—the sun and fresh air into our slum areas we should see a very marked general decline in the incidence of tuberculosis.

Rickets.

Consider next rickets. Its ætiology is unknown. There are two opposing theories as to its origin—the dietetic and the hygienic. There are those who positively assert that it is a deficiency disease; that it is due mainly to lack of fat-soluble A. There are others who as stoutly deny that diet has anything to do with it. We may leave the theorists to settle their differences and turn our attention to certain facts about it which have long been established, and certain other facts which have recently come to light. It never occurs among races living under natural conditions, and is especially prevalent among the poor in Europe and America living under so-called civilised industrial conditions—in other words, the thoroughly bad hygienic conditions of overcrowding and absence of fresh air and sunlight. Among the well-to-do it is practically unknown. In India, on the other hand, as recently shown by Hutchinson, it is a disease of the rich. It does not occur among the poor labouring class who live an open-air life, but is prevalent among the rich Mohammedans and Hindus, who are confined in airless and sunless rooms. Hutchinson discovered also this remarkable fact—that late rickets was restricted to females, who alone are confined, according to the purdah system of isolation as practised by the wealthy natives of India. Again, eminent observers in Glasgow, who have quite an exceptional acquaintance with rickets—it being, as you know, very prevalent in that city—have always associated the disease with overcrowding and lack of hygienic conditions and sunshine, which you also know are conspicuous features of that great hive of industry. According to Miss Fergusson, 50 per cent. of the children in the poor quarters of Glasgow are rickety—a vastly smaller proportion in garden cities, such as Bournville. The prevalence of rickets, she says, is associated with close confinement in tenements. Most important of all, we have the recent experiments of the Lister Institute in Vienna. They prove conclusively that a deficient diet can only produce rickets in the absence of sunlight. If abundant sunlight be present a deficient diet is powerless to give rise to it. Lastly, we have the *significant* fact that the sun's rays without any other treatment whatever can cure it—an explanation of the oft-repeated dictum that anybody can cure rickets in the summer.

All this does not prove that the absence of fresh air and sunlight is the cause of rickets; but it does prove this—that in overcrowding, confinement, want of fresh air and sunlight, we have an environment conducive to the development of rickets, either by the supply of conditions favourable to the activities of the virus, whether microbic or otherwise, or by lowering natural resistance to it. Conversely, that fresh air and sunlight and good hygienic conditions furnish an environment which is powerfully antagonistic to the disease; that they have either the power of damping down the activities of the virus whatever it is, or that they can so alter the metabolism of the body as to provide an increased resistance and immunity to it. Whichever is the method, the result is the same. These facts appear to indicate clearly and unmistakably the way to the control of this crippling and dangerous disease. And, as Mellanby says, its eradication would do away with a great deal of the bone deformity, improve the physique, lower the infantile mortality, and, most important of all, improve the teeth of the people of this country beyond recognition.

Venereal Diseases.

Let me invite your attention in the next place to venereal diseases, which have figured so largely in the public eye during recent years, are discussed in every drawing-room, exhibited at every picture-house, and with regard to the most suitable methods of controlling which there are acute differences of opinion, both among medical men and the lay public. They are the diseases of immorality. The contributing environmental factor here is the indiscriminate admixture of the sexes of all ages, a necessity of their living conditions. It is not, of course, contended that by an improvement in housing immorality would be stamped out, but it is contended that the conditions of overcrowding, without regard to age or sex, which exist in our industrial centres make the practice of morality wellnigh impossible.

Let me put before you a few facts; they are taken from the report of Dr. A. K. Chalmers, the medical officer of health for Glasgow, for 1921. There is no intention to single out that city as a sink of iniquity, or an example of a condition of things peculiarly revolting to the conscience of civilised humanity, and I have very little doubt its case could be paralleled in our own borough of Portsmouth; but I have the facts for Glasgow, and I have not similar facts for Portsmouth. In Glasgow, out of a population exceeding a million, over 600,000 live in one-roomed or two-roomed tenements. Under the heading "Sex overcrowding in small houses," Dr. Chalmers gives the following appalling examples:—

> "In a one-roomed house a father of 52 occupied the same bed with a mentally defective daughter of 24, who had an illegitimate child of 10. In another, with space for five adults, a father and daughter shared the same bed. In another a mother shared the same bed with two sons of 19 and 20 years respectively. In two-roomed houses, in one instance a son of 19 and a daughter of 21 occupied the same bed; and in another a son of 19 and a daughter of 25, who was pregnant."

However revolting these facts may be, it is right that the public should be made aware of them. This, then, being an example of the state of affairs in our industrial centres, it may be confidently stated that a great deal, at all events, of immorality and its consequences, venereal disease, is the direct result of environment—that the conditions existing make either the teaching or practice of morality impossible, and furnish the breeding ground for venereal disease.

Have we not, it may be asked, missed one phase of the problem, and are we not somewhat out of touch with the situation, with our societies for the prevention of venereal disease and for combating venereal disease quarrelling amongst themselves as to the best means of meeting the evil, and local authorities and the lay public equally divided, when conditions such as I have depicted are rampant in our midst? It is this aspect of the problem—the immorality and its consequence, venereal disease, which are the direct result of overcrowding without regard to age or sex—which I wish to lay particular stress upon here.

The Abuse of Alcohol.

Consider, lastly, the abuse of alcohol. There is no doubt that, without anything in the nature of prohibition in this country (and I believe it to be foreign to the instincts of our people to have their lives, what they may eat, and what they may drink, regulated by the policeman), there has taken place during the past 50 years a steady move *in the direction* of greater sobriety among all classes of the community. Among the upper and middle classes drunkenness was the fashion less than a century ago. It is now a disgrace. In the army, navy, and mercantile marine there was, 50 years ago, infinitely more drinking than there is to-day. In the streets of our towns the drunken man of any class is not nearly such a familiar sight as he was a generation ago. This must be attributed broadly to social evolution, to general civilising influences—better education and the inculcation of greater self-respect, which such influences promote. There are, of course, many factors at work here; but in the forefront of civilising influences is the improvement of the home. So long as the public-house is more comfortable and more attractive than a man's home, the former will claim his leisure hours. Give him a comfortable and respectable home, and the lure of the public-house will automatically diminish. In the debate on Lady Astor's Bill, a few months ago, a good deal was said about the improvement of the public-house; but nobody suggested that, by devoting greater attention to the home, we might go a long way to improving the public-house out of existence altogether. Drunkenness stands in much the same relation to bad housing conditions as immorality and venereal disease, and, moreover, is admittedly a potent factor in the dissemination of the latter.

The Economics of the Abolition of Slum Areas.

In the foregoing remarks I have endeavoured to emphasise the relation of the special environmental factors of the slum areas—lack of fresh air and sunlight, and overcrowding—to four out of five of the great endemic scourges afflicting the community at the present time. I have said nothing of their relation to epidemic diseases, though there is no doubt that some of the latter are powerfully influenced by the same factors. For instance, pneumococcus lung infection is certainly a disease mainly of cities and crowded places, the infection spreading from pre-existing cases or healthy carriers. Observations in South Africa showed that natives who had recently arrived at the mines and occupied crowded compounds were most susceptible; and Gorgas, in a report upon pneumonia in the Rand mines, draws attention to the fact that there was the same high incidence among labourers in the Panama Canal zone, until they were removed from crowded compounds and encouraged to live in separate huts. The high mortality attending measles is probably attributable to similar conditions. Epidemic disease is, however, more elusive and less under control, and for that reason I have omitted it from argument.

If, then, I have submitted evidence that, by a determined attack upon our slum areas, there would be a reasonable expectation of making a beginning of the end of four out of five of our most formidable endemic diseases, the question is, Would it be worth while? Not as a sociological venture, or on humanitarian grounds, or as a moral obligation, on any of which there would be little difference of opinion; but "would it be worth while" as a business proposition? Because, however satisfying it may be to our consciences to prate of social and moral duties to our fellow men, when it comes to doing anything, and especially to spending taxpayers' and ratepayers' money, it is usually the business and economic aspect of any question which mostly counts. It is, therefore, from this point of view only that I approach it, and I omit all moral considerations. Besides, moral values cannot be assessed in pounds, shillings, and pence, though nobody would deny that they represent a very real asset.

In a paper read at the meeting in Glasgow last year entitled "The Economics of Public Health" Lieut.-Colonel Fremantle, consulting medical officer of health for the County of Herts, by a series of calculations, estimates the total direct material loss in England and Wales from sickness and disability at a minimum of £150,000,000 a year. From tubercle alone the estimated loss is £94,000,000 a year. In the United States of America, with a population three times as great as England and Wales, the estimated cost of sickness and death is £600,000,000 a year, of which at least one-third is considered preventable. Taking the cost to this country of sickness and disablement at £150,000,000 per annum, the country could spend without loss £50,000,000 annually, or, capitalised at 5 per cent., £1,000,000,000 on clearing the slum areas and securing better housing and living accommodation, provided that the cost of sickness and disablement were thereby reduced by one-third.

What actual sum would go to the credit side of the nation's health bill it is obviously impossible to determine. It would admittedly, therefore, be a speculation. But it would not be a bogus venture. An assured dividend of considerable amount is in sight. The improved physique of the nation; its better health; the diminution certainly, the extinction possibly, of such diseases as tuberculosis and rickets; the improved moral tone of the people, and the resultant diminution of venereal disease and its consequences; decrease in the consumption of alcohol with its disastrous effects on infantile and adult mortality, with the misery and moral degradation it brings to the home, with the loss of time, increase of industrial accidents and industrial inefficiency it entails—these and other items are the prospective dividend. Whether it would or not strike £50,000,000 off the annual health bill is the speculation. In this connexion I would remind the over-cautious and those averse to any kind of speculation or any degree of risk, that it is the speculators who have made this great empire—the men of courage and enterprise, men who have faced the uncertain and the unknown, and have not been afraid to take risks. And if we have not been afraid to speculate in adventure, in arms, in trade, and in business, why should we be afraid to speculate in health?

To face the risk would require a bold and imaginative statesmanship. It does not belong to the business outlook of the parish pump, only prepared to estimate in pounds, shillings, and pence the return on the capital expenditure. It would almost certainly eventually result in a real economy to the State. What we are doing now is to provide the breeding-ground for the mass production of disease with one hand, and with the other paying out millions of the taxpayers' and ratepayers' money to deal with the end-results of the very diseases we are fostering in our midst. It has been frequently said, the people make the slums. Such a pessimistic assumption would sound the death-knell of all progress. But it is nothing more than the comfortable argument of the man selfishly indifferent to the obligations of citizenship and regardless of his duty to the body-politic. It is flatly contradicted by the fact that through all the ages man, like every other living thing, has been the product, not the cause, of his environment. The slums make the people you find in them, and the only astonishing fact is that they can breed any other sort. It is a testimony to their physique and spirit and grit, no less than to the universal natural law of the survival of the fittest, that some of the inhabitants of the slums win through such an environment and escape the moral and physical ruin which engulfs those of weaker fibre.

The industrial revolution which occurred in the last century accounted for the urbanisation of our population, and the herding together of millions of workers in our industrial centres. This has been going on ever since. The early hour at which work commenced, the long working day, entire absence of rapid transport, or rather of any transport at all, necessitated their centralisation in the heart of our great towns, where land has consequently become of greater value than health. These conditions are reversed to-day. Powerful centrifugal forces have come into play, and have come to stay. The working day as a rule begins later, the hours are shorter, the day for half the year is longer owing to the Daylight Saving Act, and the means of rapid transport are available, and are becoming increasingly available every year. It has become, therefore, practicable in many instances for the worker to live further from his work—in other words, to move from the centre towards the periphery of our large towns, where land is cheaper and where it becomes, therefore, a business proposition to build on town-planning lines, and avoid the past errors of herding human beings together like sheep in a pen or pigs in a sty.

Air Space and Sun Space.

In this connexion it would seem that the first and most essential requirement in future building is to reduce the density of the houses—in other words, the number to the acre; and it is disappointing, and in the opinion of many a grave defect in the Government's last Housing Bill, that no such restriction appears. In submitting town-planning schemes, however, local authorities have, under the Housing Acts, powers to regulate for this, and a memorandum from the Ministry of Health suggests 12, 10, or 8 houses to the gross acre as suitable density requirements according to the nature of the neighbourhood. If this in the opinion of the Ministry is the correct requirement for health, what are we to say about houses built 40 or more to the acre? The only answer is that they should be swept away wholesale at the earliest possible opportunity.

The air space and sun space round the house is of infinitely more importance than the size of the house itself, or whether it contains a parlour or not. The cramped crofter's cottage does not produce rickets and tuberculosis, because his children live mostly in the sun and air round their dwelling; but children "cabined, cribbed, confined" in the dark sunless and airless environment of our large towns are inviting both all the time. The most important educational requirement of domestic hygiene and its highest fulfilment is the open window, night and day, summer and winter. It is astonishing how quickly the human organism abjures the hothouse conditions of civilised living and adapts itself to its natural environment, fresh air. The tuberculous patient, after three months' open-air treatment in a sanatorium, cannot endure the closed window in his own home. The tuberculous children at Leysin in Switzerland, and at Alton and Hayling Island in this country, live practically naked in the open air, and by that habit and that habit alone throw off a most formidable and deadly disease. Why, then, all the care of healthy children, with their active metabolism capable of adapting itself to almost any requirement, to wrap them up in the warmest of clothing, confine them in hot rooms with windows shut, keep every draught from their bodies, and submit them to general hothouse conditions suitable only to the old whose metabolism is barely sufficient to keep body and soul together, and whose clock has almost run down?

Modern civilisation is suffocating itself in the polluted atmosphere and darkness of our great industrial cities. The need of pure air and sunlight, of which there is plenty about, and to be had for nothing, was never so insistent as it is to-day. These great gifts of nature were plentifully supplied to primitive man, and were his *only* sure defence against disease. They are as bountifully given to civilised man, but he seems to have lost sight of their value, or to have deliberately turned his back on them, while he requires a whole volume for the mere nomenclature of his innumerable diseases.

Sociology and Medicine.

Perhaps apology is needed for touching to-night on a problem which may be considered rather a sociological one than one of strictly scientific medicine. But apart from the fact that I believe a wide latitude is permitted in the Presidential Address to this Association, my choice of subject can, I think, be justified by both local and general as well as scientific considerations. First of all, it does not seem to be an unfitting subject to bring to your notice in the town which bred Charles Dickens and Walter Besant, who devoted their unrivalled literary talents to depicting scenes and characters drawn from our slums, and such as our slums are only too familiar with. Secondly, although this borough has witnessed some of the most brilliant pageants and displays in the history of this country, and although you are sitting here in what we are proud to think is one of the finest town-halls in the kingdom, yet there is an obverse to the shield, and round the corner we can introduce you to slums as pestilential and overcrowded as any to be found in the land. Further, although the environment of the wage-earning classes, in our industrial centres, and its effects may in part be a sociological question, I have endeavoured to show that it is inseparably linked up with, and *is* in fact the greatest of all our problems of preventive medicine, the most rational and the most scientific of all medicine. And if this is so, then it is up to the medical profession, both individually and through this great Association of medical men, to educate and lead public opinion in this matter, and to strengthen the hands of governments and local authorities, on whom will ultimately devolve the responsibility, no less than the odium, of providing the remedy. Concentration on the prevention of disease, on strengthening resistance to disease, by the improvement of environment, rather than on the search for cures or palliatives when the damage is already done; more attention to stimulating and fortifying the natural defensive mechanisms against disease, less to direct attack on disease itself; as Professor Wynne so ably put it last year, concentration on the environment rather than on the individual—this appears to me to be the most scientific, the most economical, and the most productive means of combating the worst of the evils from which the community suffers. If, in conclusion, I might sound a personal note, it is this—that as Chairman of the Health and Housing Committee of this great borough, by the goodwill of my colleagues on the Council, this is a conclusion forced upon me by no mere theoretical considerations, but by an everyday acquaintance with undeniable facts.

PRIMARY AND SECONDARY RESISTANCE TO THE INDUCTION OF CANCER.[1]

BY J. A. MURRAY, M.D., B.SC. EDIN.,
DIRECTOR, IMPERIAL CANCER RESEARCH FUND, LONDON.

I.—PRIMARY RESISTANCE.

THE researches on experimental carcinogenesis of the past ten years have familiarised pathologists with the constancy with which a continuation of the effective stimulation over a considerable time is essential to successful induction of cancer. This feature of the course of such experiments harmonises with the chronic character of the irritations which clinical experience of the disease in man and animals has shown to be nearly universal in those forms of the disease where such a nexus can be inferred. Taken in conjunction with the histological identity of the lesions, it gives us reasonable assurance of the fundamental identity of the processes involved in cancer as it occurs naturally and under experiment. Of all the methods which have been used to produce cancer in experimental animals (X rays, animal parasites, tar, paraffin, arsenic) the application of tar, or tar products, has been most widely employed, and our knowledge of its action is correspondingly extensive. In what follows this is the only method to which reference will be made, but it must be clearly understood that once malignant growth has been started by this means, there are no characters, clinical or microscopic, by which the tumours can be distinguished from those of the same tissue produced by other agencies or arising spontaneously—i.e., without known association with external agencies.

The length of time which elapses from the beginning of tarring till real autonomous growth sets in shows great variation even in animals of the same species. In the mouse this interval may be as short as three months, or as much as 18 months, and in one experiment a mouse remained free from growth, although tar had been applied to the same area twice weekly for more than 18 months. The majority of mice, to social evolution, to general civilising influences—better education and the inculcation of greater self-respect, which such influences promote. There are, of course, many factors at work here; but in the forefront of civilising influences is the improvement of the home. So long as the public-house is more comfortable and more attractive than a man's home, the former will claim his leisure hours. Give him a comfortable and respectable home, and the lure of the public-house will automatically diminish. In the debate on Lady Astor's Bill, a few months ago, a good deal was said about the improvement of the public-house; but nobody suggested that, by devoting greater attention to the home, we might go a long way to improving the public-house out of existence altogether. Drunkenness stands in much the same relation to bad housing conditions as immorality and venereal disease, and, moreover, is admittedly a potent factor in the dissemination of the latter.

---

[1] Read at the Cancer Congress at Strasbourg on July 23rd, 1923.

The Economics of the Abolition of Slum Areas.

In the foregoing remarks I have endeavoured to emphasise the relation of the special environmental factors of the slum areas—lack of fresh air and sunlight, and overcrowding—to four out of five of the great endemic scourges afflicting the community at the present time. I have said nothing of their relation to epidemic diseases, though there is no doubt that some of the latter are powerfully influenced by the same factors. For instance, pneumococcus lung infection is certainly a disease mainly of cities and crowded places, the infection spreading from pre-existing cases or healthy carriers. Observations in South Africa showed that natives who had recently arrived at the mines and occupied crowded compounds were most susceptible; and Gorgas, in a report upon pneumonia in the Rand mines, draws attention to the fact that there was the same high incidence among labourers in the Panama Canal zone, until they were removed from crowded compounds and encouraged to live in separate huts. The high mortality attending measles is probably attributable to similar conditions. Epidemic disease is, however, more elusive and less under control, and for that reason I have omitted it from argument.

If, then, I have submitted evidence that, by a determined attack upon our slum areas, there would be a reasonable expectation of making a beginning of the end of four out of five of our most formidable endemic diseases, the question is, Would it be worth while? Not as a sociological venture, or on humanitarian grounds, or as a moral obligation, on any of which there would be little difference of opinion; but "would it be worth while" as a business proposition? Because, however satisfying it may be to our consciences to prate of social and moral duties to our fellow men, when it comes to doing anything, and especially to spending taxpayers' and ratepayers' money, it is usually the business and economic aspect of any question which mostly counts. It is, therefore, from this point of view only that I approach it, and I omit all moral considerations. Besides, moral values cannot be assessed in pounds, shillings, and pence, though nobody would deny that they represent a very real asset.

In a paper read at the meeting in Glasgow last year entitled "The Economics of Public Health" Lieut.-Colonel Fremantle, consulting medical officer of health for the County of Herts, by a series of calculations, estimates the total direct material loss in England and Wales from sickness and disability at a minimum of £150,000,000 a year. From tubercle alone the estimated loss is £94,000,000 a year. In the United States of America, with a population three times as great as England and Wales, the estimated cost of sickness and death is £600,000,000 a year, of which at least one-third is considered preventable. Taking the cost to this country of sickness and disablement at £150,000,000 per annum, the country could spend without loss £50,000,000 annually, or, capitalised at 5 per cent., £1,000,000,000 on clearing the slum areas and securing better housing and living accommodation, provided that the cost of sickness and disablement were thereby reduced by one-third.

What actual sum would go to the credit side of the nation's health bill it is obviously impossible to determine. It would admittedly, therefore, be a speculation. But it would not be a bogus venture. An assured dividend of considerable amount is in sight. The improved physique of the nation; its better health; the diminution certainly, the extinction possibly, of such diseases as tuberculosis and rickets; the improved moral tone of the people, and the resultant diminution of venereal disease and its consequences; decrease in the consumption of alcohol with its disastrous effects on infantile and adult mortality, with the misery and moral degradation it brings to the home, with the loss of time, increase of industrial accidents and industrial inefficiency it entails—these and other items are the prospective dividend. Whether it would or not strike £50,000,000 off the annual health bill is the speculation. In this connexion I would remind the over-cautious and those averse to any kind of speculation or any degree of risk, that it is the speculators who have made this great empire—the men of courage and enterprise, men who have faced the uncertain and the unknown, and have not been afraid to take risks. And if we have not been afraid to speculate in adventure, in arms, in trade, and in business, why should we be afraid to speculate in health?

To face the risk would require a bold and imaginative statesmanship. It does not belong to the business outlook of the parish pump, only prepared to estimate in pounds, shillings, and pence the return on the capital expenditure. It would almost certainly eventually result in a real economy to the State. What we are doing now is to provide the breeding-ground for the mass production of disease with one hand, and with the other paying out millions of the taxpayers' and ratepayers' money to deal with the end-results of the very diseases we are fostering in our midst. It has been frequently said, the people make the slums. Such a pessimistic assumption would sound the death-knell of all progress. But it is nothing more than the comfortable argument of the man selfishly indifferent to the obligations of citizenship and regardless of his duty to the body-politic. It is flatly contradicted by the fact that through all the ages man, like every other living thing, has been the product, not the cause, of his environment. The slums make the people you find in them, and the only astonishing fact is that they can breed any other sort. It is a testimony to their physique and spirit and grit, no less than to the universal natural law of the survival of the fittest, that some of the inhabitants of the slums win through such an environment and escape the moral and physical ruin which engulfs those of weaker fibre.

The industrial revolution which occurred in the last century accounted for the urbanisation of our population, and the herding together of millions of workers in our industrial centres. This has been going on ever since. The early hour at which work commenced, the long working day, entire absence of rapid transport, or rather of any transport at all, necessitated their centralisation in the heart of our great towns, where land has consequently become of greater value than health. These conditions are reversed to-day. Powerful centrifugal forces have come into play, and have come to stay. The working day as a rule begins later, the hours are shorter, the day for half the year is longer owing to the Daylight Saving Act, and the means of rapid transport are available, and are becoming increasingly available every year. It has become, therefore, practicable in many instances for the worker to live further from his work—in other words, to move from the centre towards the periphery of our large towns, where land is cheaper and where it becomes, therefore, a business proposition to build on town-planning lines, and avoid the past errors of herding human beings together like sheep in a pen or pigs in a sty.

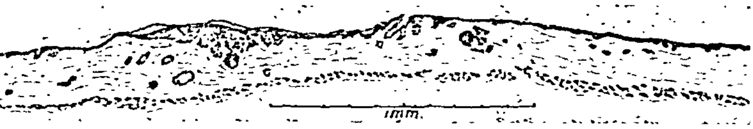

FIG. 1.—Slight proliferative changes at margin of tarred area of skin in a mouse which had spontaneous mammary carcinoma excised. Duration of tarring, 23 weeks.

2

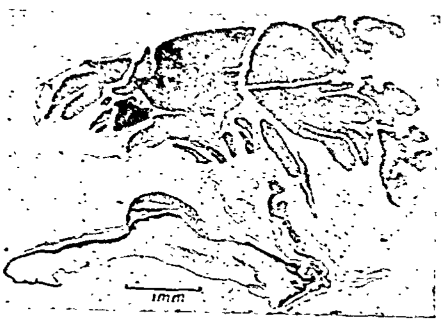

FIG. 2.—Absence of new growth in area tarred with ethereal extract in the mouse in which the alcoholic extract had produced the carcinoma shown in Fig. 3.

3

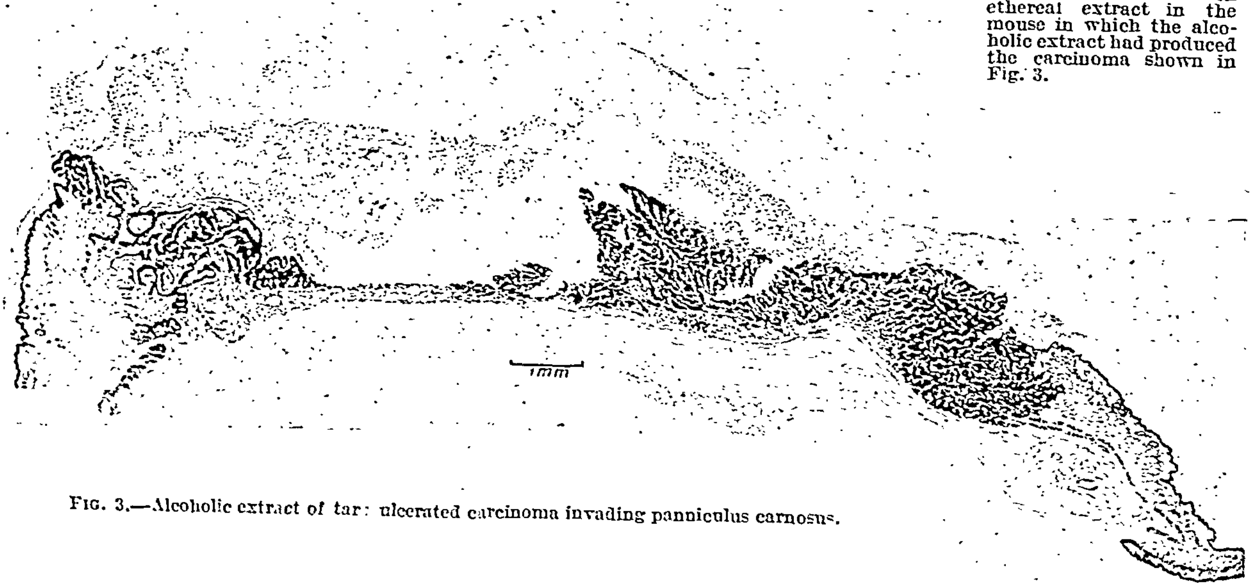

FIG. 3.—Alcoholic extract of tar: ulcerated carcinoma invading panniculus carnosus.

4

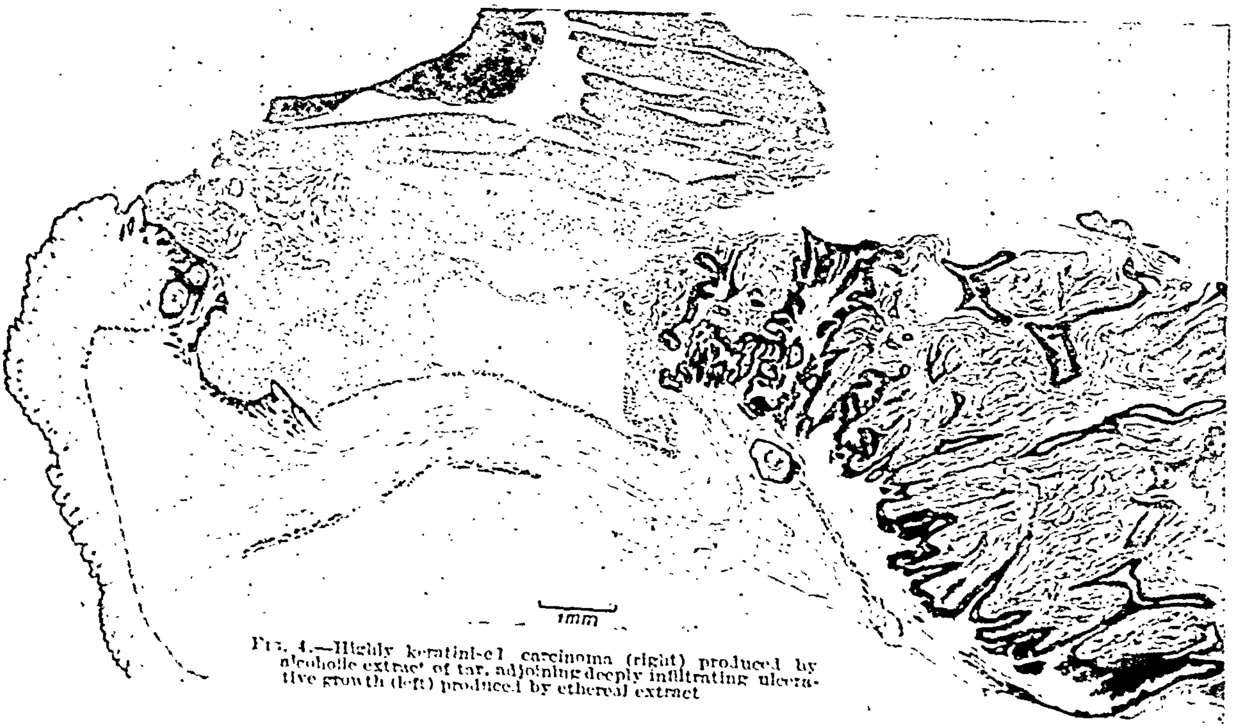

FIG. 4.—Highly keratinised carcinoma (right) produced by alcoholic extract of tar, adjoining deeply infiltrating ulcerative growth (left) produced by ethereal extract

however, develop skin carcinomata within six to nine months of tarring applied twice weekly. The extent of the area painted appears to have little influence. Very similar results have been obtained by painting the whole dorsal surface of the animal (Deelman), or an area of a square centimetre (Fibiger and Bang) or less (Murray and Woglom). The frequency of the applications, as might be expected, affects both the rapidity of induction and the percentage of success. Even a reduction from twice to once weekly prolongs considerably the interval necessary to produce cancer in mice, and the majority of workers have made their applications on alternate days or three times a week.

An interesting question is whether there is an upper limit to the intensity of the stimulation which may be followed by cancer production. In an experiment on rabbits in this laboratory it was found that bi-weekly applications of ethereal extract of tar to a small area on the nape of the neck produced highly inflamed and painful excoriations within a month. The applications were discontinued for two to three weeks, and then begun again, but only once weekly. The irritative phenomena did not recur, but after six to eight months from the beginning of the experiment—two rabbits out of 15 showed localised progressive lesions which continued after painting was stopped, and proved to be typical squamous-cell carcinomata when examined microscopically after excision. When it is remembered that Yamagiwa and Ichikawa had to persevere for two years to produce carcinoma of the rabbit's ear and that neither Fibiger nor Leitch (personal communications) have obtained progressive autonomous growths after the same length of time in the same species, the suspicion seems justified that the success in this experiment was in part due to the less severe and more widely spaced stimulation. As pointing in the same direction, it may be mentioned that cancer has never been observed in the workers in chromic acid factories, in whom chronic ulcerations, known as chrome sores, are common. Then again, X ray cancer has rarely supervened at the site of X ray burns and never after radium burns, but rather in areas subjected repeatedly to slight amounts of irradiation. Contrast also the occurrence of carcinoma of the skin in locomotive engine-drivers exposed to the irradiation from the open fire-box with the fact that the much more intense stimulation of the finger-tips by pipe-smokers in pressing down the glowing tobacco is apparently never followed by cancer.

According to Deelman, the association of another kind of injury with tarring results in a shortening of the time necessary to produce cancer. Deelman scarified the dorsal surface of mice immediately before tarring. The treatment was carried out on alternate days for a week and then tarred without scarification thrice weekly for one month. Papillomatous new growths, going on to malignant new growth, supervened after five to eight weeks after the beginning of the experiment—i.e., roughly one-quarter of the time necessary without scarification. Deelman considers that scarification merely permits a more intimate application of the tar to the deeper layers of the skin, but the following observations suggest that a more fundamental significance should be attributed to it. When the area scarified and tarred is small the time of cancer production is not shortened in anything like the proportion obtained by Deelman. It is also significant that he found that repetition of scarification after the first week did not further accelerate the onset of neoplastic change. It is as if the trauma, and the reparative changes following it, had put the cells in a more receptive condition for the carcinogenetic action of the tar.

The relation of trauma to the induction of new growth is further illuminated by the work of Drew on the mechanism of repair by the method of tissue culture. It has been known for a long time that actively growing embryonic tissues, and tumours also, proliferate immediately when placed in a suitable medium outside the body. The quiescent tissues of the young or adult animal, on the other hand, do not begin to grow till after the lapse of an interval more or less prolonged. Thus, Drew found that heart or kidney of the rat may lie dormant for from 10 to 14 days in a medium in which the corresponding embryonic tissues, and tumours, would have shown vigorous growth in 24 to 48 hours. When a filtered saline extract of disintegrated rat kidney which has been incubated at 37° C. for two to four hours is added to the culture-medium, adult tissues begin growing at once and in 48 hours spread out on the cover-glass in a sheet of healthy dividing cells. The initial delay has been eliminated. If the disintegrated kidney instead of being incubated is maintained at 0° C. for two hours and then filtered off, the fluid is devoid of this actively stimulating property. When a corresponding cold extract is prepared from a rapidly growing transplantable carcinoma or sarcoma of the mouse it is found to be as rich as, or richer than the extract of incubated damaged normal tissue, in the activating substances. From these observations, many times repeated and always with the same result, it is concluded that these malignant growths produce continuously of their own accord growth-stimulating substances which normal tissues only elaborate in response to cell damage. A direct relation exists between the growth-stimulating power of the tumour extracts and the rate of growth of the tumour used to prepare it. This suggests strongly that the biochemical mechanism by which their proliferation is maintained is, at any rate in part, by the elaboration of this growth-activating substance or substances. It is not desirable to attempt, at the present stage of these investigations, a speculative development of this conception of the nature of neoplastic proliferation further than to point out how well it accords with the additive effect of trauma in accelerating carcinogenesis as shown by Deelman. A certain amount of activating substance is probably produced by any kind of cell damage, and when by constant repetition this production has become automatic, proliferation will continue after removal of the cause of protoplasmic disintegration. Temporary hypertrophies would, in this conception, correspond to the purely reactive production of activator, ceasing when the irritant is removed, benign growth to an autonomous production in small amount, and malignant growth to a more abundant production.

In the past one has been accustomed to regard the preparatory period of chronic irritation which precedes the development of cancer as occupied in a gradual cumulative removal of resistance on the part of the organism to the unrestricted powers of growth of its constituent cells. This resistance, variously designated by inhibition, internal tissue tension, and similar fantastic expressions, was regarded as holding the tissues in check. The preceding discussion leads to a somewhat different conception—viz., that in cancer the cell acquires new properties, exploitations, if you will, of the normal cell activities, but acting in a new way with disastrous consequences to the organism.

Two other features of the development of cancer under experimental conditions bear on this conception of the secondary character of the neoplastic transformation. The first is the discrete focal character of the process. Growth begins in isolated, usually minute, areas and not diffusely throughout the whole zone of application of tar. The second is the existence of a latent period, very little affected by continuation of the irritant as indicated by Deelman's work and emerging clearly from the deliberate experiments of Leitch and of Bang. These authors working independently stopped the application after two, three, or more months in animals which had shown no proliferative changes or only slight hyperplasias, and found cancer appearing after a further interval at the treated site. In several instances the local hyperplasia had regressed and the skin had become smooth and the new growth started in the otherwise normal hairless area.

experiment, admittedly difficult to interpret, gives indications of a mutual influence of approximately contemporaneous tumours, by which their full cancerous development is retarded for a time or permanently. The other experiments show that the induction of a fresh primary growth after a first has been definitely established meets with a very intense resistance, whether the first tumour be of the same parent tissue or another. The nature of this secondary refractoriness to the induction of cancer is obscure. It is not a resistance to growth, as is shown by the occurrence of metastases and the success of autoplasty. It is apparently an inability to react with cancerous proliferation to procedures which initiate it with certainty in normal animals. Nor has it anything in common with the well-known acquired resistance to the growth of transplantable tumours. Fibiger has produced experimental tar cancer in such resistant animals, and the development spontaneously of mammary carcinoma has also been recorded in these so-called "immunes."

The nature of this refractory state must be the subject of further investigation. The rarity of multiple primary malignant new growths in the same individual finds a rational explanation by it. Its greatest interest and importance, however, lies in the indication it gives of a systemic, constitutional change in the organism in which cancer has developed, a change which, if it could be recognised with certainty and rapidity, would enable us to recognise cancer in its earliest stages, and could we produce it without initiating new growth, would place in our hands a rational means of prevention.

THE IMMEDIATE PROGNOSIS IN NEPHRITIS,

WITH SOME REMARKS ON URÆMIA.

By O. L. V. DE WESSELOW, M.B. OXF., F.R.C.P. LOND.,
CHEMICAL PATHOLOGIST, ST. THOMAS'S HOSPITAL, LONDON.

WITH the increasing application of chemical methods to the study of the disease, the accuracy of our prognosis in nephritis has made a considerable advance. The bulk of modern work has centred round the question of the retention of the nitrogenous waste products in the blood, and has more especially concentrated on the content of the blood in urea, on account of the ease and accuracy with which this substance can be estimated. There can be no doubt, however, that an estimation of the urea content of the blood in cases of severe azotæmic nephritis does not necessarily settle the question of the immediate prognosis. A blood-urea content as high as 300, or even, in rare instances, 400 mg. per 100 c.cm., is not incompatible with recovery in an acute case, and even in chronic types of nephritis, in which the capacity for recovery is of necessity less, a blood-urea content of 100 to 200 mg. does not necessarily imply a speedy death. A confident prognosis can therefore scarcely be ventured upon from an estimation of the blood-urea alone, and several estimations at intervals of some days may be necessary before an opinion on the immediate outlook can be given.

That this difficulty does actually exist in practice is shown by the stress laid by certain American authors on the creatinine content of the blood. Creatinine is assumed by these workers to be more readily excreted by the kidney than either uric acid or urea, and is, therefore, the last of the nitrogenous waste products to accumulate in the blood. On this assumption, any marked creatinine accumulation is to be regarded as indicative of very severe renal functional impairment, and of the terminal stage of the disease. The whole question of the accuracy of the creatinine estimation has, however, been reopened by Benedict,[1] who has even gone to the length of suggesting that practically no creatinine is present in the blood, though he believes that the estimation of the substance, whose chromogenic reactions have led to its confusion with creatinine, is still of value. Folin,[2] also, has come to the conclusion that the retention of the various nitrogenous waste products in the azotæmic type of nephritis proceeds pari passu, and that the suggested delayed retention of creatinine does not actually occur.

A plea may therefore be entered for the value of a determination of the plasma content in inorganic phosphorus (phosphate) in estimating the probable outcome of a case of azotæmic nephritis. The phosphate estimation by the method of Bell and Doisy,[3] as modified by Lehmann, is simple, rapid, and apparently accurate; and, while there is no evidence that the nitrogenous waste products exert any toxic influence upon the organism, phosphate retention is associated with certain definite chemical changes in the blood, which are apparently of importance in the symptomatology of uræmia. The retention of the nitrogenous waste products is a useful guide to the degree of renal damage present, but in itself is apparently harmless; phosphatic retention, on the other hand, appears to involve certain deleterious results.

Though retention of phosphates is undoubtedly associated with impairment of nitrogenous excretion, and though, when a series of cases is averaged, it is found that the rise in the plasma phosphate closely corresponds to the degree of urea retention, in individual cases marked differences in the degree of retention of the two bodies occur. Thus we may find a high blood-urea with a relatively low plasma phosphate content, and conversely. The cause of these differences in the degree of retention of the two bodies is uncertain; the available evidence would appear to suggest that they are the results not so much of variations in excretion as of variations in the diet, and in the demand for phosphorus and nitrogen for anabolic purposes.

Value of Estimation of Inorganic Phosphorus.

The value of the estimation of the inorganic phosphorus in prognosis is illustrated in Table I., in which the figures for blood-urea and plasma phosphorus in 53 consecutive cases of nephritis are tabulated. Where a series of estimations have been made in a patient, the highest figures obtained for the urea and phosphorus are given. In all the fatal cases death resulted from true uræmia. Two cases of nephritis, in which the disease was complicated by peritonitis and by portal pyæmia, and which terminated fatally, have been omitted; in both of these the plasma phosphate content showed no appreciable rise. The normal inorganic phosphorus amounts to between 2 and 4 mg. per 100 c.cm. of plasma.

TABLE I.—*Blood-urea and Plasma Phosphorus in 53 Consecutive Cases of Nephritis.*

Blood-urea mg. per 100 c.cm.	Cases.	Deaths.	Plasma phosphates as mg. P per 100 c.cm.	Cases.	Deaths.
400–566	6	6	10–22	12	12
300–400	3	2	8–9	2	1
200–300	4	3	7–8	2	—
100–200	7	2	6–7	2	—
50–100	7	—	5–6	7	—
Below 50	26	—	Below 5	28	—

The number of fatal cases is small, but the conclusion as to the prognostic value of the phosphate estimation appears to be justified. A sharper line separates the fatal from the non-fatal cases from the standpoint of the plasma phosphorus than from the standpoint of the blood-urea. It is not, of course, suggested that a plasma inorganic phosphorus content exceeding 10 mg. per 100 c.cm. *invariably* implies a speedy death, but merely that as regards the immediate prognosis the degree of phosphate retention is a better guide than the degree of urea retention.

II.—SECONDARY RESISTANCE TO CANCER PRODUCTION.

The strict localisation of experimental tar cancer to the area painted would lead one to expect that subsequent tarring of another area remote from the first would again result in the production of a fresh primary growth at the new site. As a rule, experiments of this kind end prematurely by the death of the animal from intercurrent disease or from metastasis in internal organs from the first primary growth. For this reason, although these attempts have been carried out for more than two years in more than 50 mice in which experimental tar cancer had been produced, the number in which the second tarring was at all commensurate in duration with the first is still very small. Table I. gives the duration of the first tarring, the interval between the two series of applications, and the duration of the second tarring.

TABLE I.

Identification number.	Duration of first tarring.	Interval.	Duration of second tarring.
1577	25 weeks	36 weeks	24 weeks
1632	58 ,,	8 ,,	25 ,,
1717	28 ,,	12 ,,	29 ,,

In none of these mice was there any indication of proliferative changes at the secondary site. The hair fell out in the treated area and the skin was found to be atrophic when it was examined in sections. Taken by themselves these observations are without significance, except incidentally for the doubt they throw on the presumed predisposing action of age as increasing the liability to cancer, if no other factor be assumed to operate. The result of a similar trial in mice with spontaneous mammary cancer, however, increases the probability that these negative results are not fortuitous, but due to a real unsusceptibility of the animals to the carcinogenetic action of tar. Table II. gives the duration of the tarring of mice in which spontaneous mammary carcinoma had been removed by operation.

TABLE II.

A = Identification number. B = Duration of tarring in weeks.

A		B	A		B	A		B
1595	....	20	1649	....	20	1758	....	14 S
1601	....	23	1655	....	21	1760	....	25 S
1620	....	22	1737	....	37 S	1777	....	11 S
1635	....	17	1755	....	18 S	1787	....	8 S
1641	....	24	1757	....	9			

Result.—No. 1755: Metastases in lungs. No. 1787: Papilloma growing progressively after cessation.

S = *Scarification (see context).*

In those marked "S" in the column giving the duration of tarring, scarification was combined with the application of tar either for the whole or part of the time. The result after eight weeks in mouse No. 1787 is taken to indicate that the failure to produce any proliferative changes was not due to insufficient duration or intensity of the applications, but indicates a real inability of these animals to respond to this stimulation, carcinogenic for normal animals. (See Fig. 1.)

Another experiment was carried out to see how long the first stimulation must precede the second in order to prevent the development of cancer from the latter. This experiment is still in progress and only the first provisional results in six mice out of 50 tested are available. These 50 mice were painted twice weekly on the left shoulder with the ethereal extract of tar with which most of these experiments have been performed. Seven weeks after the beginning of the tarring, applications were begun on the right flank, unaltered hairy skin intervening between the two areas. The result up to the present is shown in Diagram A.

In two mice carcinomata have developed at both sites and practically simultaneously. In the other four no growth has been produced at the second site, although in all but one which died early, tarring has been kept up for a period, as long as, or longer than, was necessary in the first instance.

Some of the peculiarities in the results of another experiment, planned originally to show the relative carcinogenic efficacy of the alcohol soluble, and of the ether soluble fractions of tar in comparison with the unaltered whole tar, bear out this conclusion of a general systemic effect of the development of one primary growth, on the liability of the animal to develop another primary growth. The experiment was begun before this possibility had been suspected. Unaltered whole tar, alcoholic extract, and ethereal extract of tar were applied simultaneously to separate areas of the dorsal skin of 60 normal mice. After four months, when the first tumour appeared, 50 mice survived, and in these 25 presented malignant new growths distributed as follows:—

DIAGRAM A.

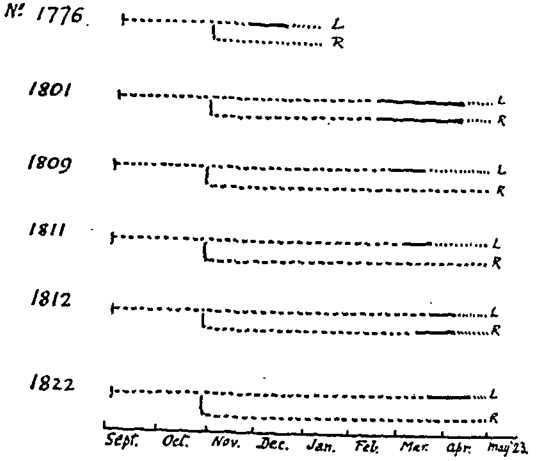

Diagram showing development of carcinomata in six mice painted twice weekly on left shoulder with ethereal extract of tar, and seven weeks later also painted on right flank.

25							

Twenty-two out of 25 animals bore carcinomata at the site painted with the ethereal extract and in 11 of these no tumours developed at the other sites painted. Twelve had carcinomata at the site treated with the original tar, and of these ten had growths at the area treated with ethereal extract, two only having no tumours elsewhere. Only two mice developed tumours at the site painted with the alcoholic extract. In one of these (No. 1710, Fig. 4) the ethereal extract also produced a tumour. In the other, only a slight warty thickening appeared at the site treated with the ethereal extract. (Figs. 2 and 3.) While the ethereal extract is definitely more certain, it is not more speedy in its action than unaltered tar. Both preparations are more active than the alcoholic extract and yet the latter in one mouse alone gave rise to a carcinoma. (Figs. 2 and 3.)

This experiment shows that when several substances of different carcinogenic power are applied simultaneously to separate areas of skin, the result cannot be predicted with certainty from a knowledge of their respective strengths. The relatively weaker whole tar may inhibit for a time the development of the tumour produced by the more active ethereal extract. In one mouse the very much less efficient alcoholic extract had produced a tumour which grew progressively, while the ethereal extract lesion remained stationary. Taken in conjunction with the results of the retarring of tumour mice already described, this typical of true uræmia are absent, and in contrast with the latter condition the prognosis in both eclamptic and nephritic types is good, provided that death does not result from the convulsions. The ultimate renal recovery is, as a rule, complete. The whole root of the matter would appear to lie in the cause of the raised blood pressure in the pseudo-uræmic cases, and of this no satisfactory explanation can as yet be given. The rapid changes in the height of the blood pressure appear to preclude anatomical changes in the vessel walls as a factor; the influence of the hydræmic plethora is doubtful, since marked hydræmia does not necessarily involve a rise in the systolic pressure; the most plausible explanation would appear to lie in the presence of some as yet undetermined pressor substance in the circulation, but such an explanation is at present mere hypothesis. It must even be admitted that we have, as yet, no definite evidence that the renal lesion in these cases is primary. The reported occurrence of a rise of blood pressure in the eclamptic type of pregnancy toxæmia before albumin appears in the urine is of interest in this connexion.

Lastly, in subacute nephritis the two types of uræmia may coexist, and this fact has, in the past, led to considerable confusion. In such cases a raised blood pressure, hydræmia, and convulsions are combined with retention of nitrogenous waste products and phosphates, and with depletion of the plasma bicarbonate and serum calcium. In such cases the prognosis is of the worst. The condition can only be distinguished from eclamptic pseudo-uræmia by the chemical examination of the blood, which at once reveals the true condition of affairs.

For the sake of clarity, the findings in the three conditions are summarised in Table III.

TABLE III.—*Findings in Three Types of Uræmia.*

	Blood	Plasma.		Serum.		B.P.
—	Urea mg. per 100 c.cm.	Phosphates as mg. P per 100 c.cm.	CO_2 vols. per 100 c.cm.	Calcium mg. per 100 c.cm.	Solids per cent.	Systolic.

SECONDARY ANÆMIA IN INFANCY:

A RECORD OF SOME CLINICAL OBSERVATIONS.

By HELEN M. M. MACKAY, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN, AND TO THE INFANTS HOSPITAL, LONDON.

SECONDARY anæmia has long been recognised as of common occurrence in infancy, and undoubtedly results from many and diverse causes. The present article is concerned with the condition seen in a group of infants otherwise in good or fairly good health, who were receiving a diet consisting chiefly of cow's milk, with or without heavy carbohydrate additions.

Milk Diet as a Cause of Anæmia in Infants.

Anæmia in subjects on such diets has been frequently described, but opinion as to its cause and symptomatology shows wide variation. Milk contains an extremely small amount of iron, a quantity insufficient for the needs of the growing infant (Morse and Talbot[1]), and the amount present in cow's milk is probably even less than that in human milk (Finkelstein[2]). The percentage of iron retained is apparently less in a baby fed on cow's milk or goat's milk than in one fed on human milk (Krasnogorski[3] and Blauberg[4]), so that the amount of iron obtained from a milk diet by a bottle-fed baby does not nearly suffice to meet its needs. Bunge[5] has shown that there is in the liver of young animals at birth a store of iron, which makes good this deficiency in milk during the period of lactation, and that this store diminishes progressively in amount during the time of milk feeding. In the infant it has been demonstrated that two-thirds of this store of iron is deposited during the last three months of intra-uterine life, so that a premature infant is born with a small store of iron, though the percentage per kilo body weight is approximately the same as in the full-term child (Hugouenq[6]). Premature infants are specially liable to anæmia, and some authors have held that every premature infant fed exclusively on milk becomes anæmic, as it is born before a sufficient amount of iron has been accumulated in the liver (Schultness[7]). Many workers claim excellent results from the administration of inorganic iron salts by mouth in this condition. Schwarz and Rosenthal,[8] for instance, say that they are able to bring about an increase of 20–30 per cent. hæmoglobin in a few weeks by the administration of iron alone. The majority of writers (e.g., Schultness,[7] Finkelstein[2]), however, advise a restriction of the quantity of milk in the diet and more mixed feeding besides treatment with iron salts. Most of the French authors (e.g., Hallé and Jolly,[9] Leenhardt[10]) consider that the type of anæmia produced in infants by an insufficiency of iron in the diet resembles chlorosis as seen in young adults, and have called it the "chlorotic type" of anæmia in young children.

Certain German authors have differed entirely from these views. Kleinschmidt,[11] after an exhaustive summary of the literature and an examination of his own cases, arrived at the conclusion that the condition resulting from a one-sided milk dietary, which he terms "alimentary anæmia," presents a very varied picture. There are all gradations in the blood between the "chlorotic type" (showing a normal number or slight reduction of red cells, with a diminution in the percentage of hæmoglobin and little other change in the blood) and cases of well-marked von Jaksch's anæmia, with the profound changes in the blood together with the large hard spleen associated with this disease. He, like Czerny, does not favour the administration of iron salts. Both hold that excessive milk consumption plays an important part in anæmia in infants. Czerny believes that the saponification of a large amount of milk fat causes diminution in the alkaline reserve, and Kleinschmidt, while admitting that this view is not yet proved, is nevertheless of opinion that the anæmia is due to some toxic effect produced by the milk in the food. Both successfully treated the condition by greatly reducing the quantities of milk, replacing it by vegetables, cereals, fruit, and, if possible, meat, but very little fat. Kleinschmidt recognises, however, that such a diet contains much more iron than a milk dietary. He holds that "alimentary anæmia" occasionally results from excessive carbohydrate feeding, and attributes this also to a toxic effect. He does not think that anæmia invariably develops from a long-continued and exclusive milk dietary, but believes that its development is favoured by constitutional abnormalities and debility. In a recent publication from the Johns Hopkins Hospital, Evans and Happ[12] set forth evidence in favour of the view that secondary anæmia in infancy from a single cause may lead to a variety of blood pictures, the grade of change depending on the degree of strain thrown upon the blood-forming mechanism. So that they agree with Kleinschmidt that there is no clear line of demarcation between the "chlorotic type" of anæmia of infancy

As an illustration of this, Table II. gives the parallel figures for a small number of fatal and non-fatal cases.

TABLE II.—*Blood-urea and Plasma Phosphorus in 5 Fatal and 5 Non-fatal Cases.*

Fatal.			Non-fatal.	
Urea.	Plasma P.	Length of survival in days.	Urea.	Plasma P.
269	17·5	3	150	5·0
171	15·1	7	196	7·0
198	14·2	3	223	5·6
238	11·6	4	167	6·7
429	12·0	2	267	8·8

Apart from the question of the immediate prognosis, phosphate retention is apparently more definitely connected with the symptoms of true uræmia than is the retention of urea. Cases are occasionally encountered in whom both phosphate and urea retention are present, and in whom the plasma phosphate shows a temporary fall without a corresponding drop in the blood-urea. Under such conditions the symptoms of uræmia may largely disappear during the period of the phosphate fall, in spite of the persistence of a high blood-urea content. Though the weight of experimental evidence would appear to be against the existence of a definitely toxic action of the phosphate ion, its increase in the blood is associated with certain changes in the chemical composition of that fluid which are probably of importance to the organism. The first of these is a reduction in the bicarbonate content of the plasma, often extreme and proportionate to the increase in the plasma phosphate[4]; the second, possibly of more significance, is a reduction of the serum calcium. In the present series the lowest calcium content observed was 5·1 mg. per 100 c.cm. of serum, or about half the normal. The calcium decrease was, on the average, proportional to the increase in the phosphate content of the plasma, and is probably the result of that increase, since experimentally injections of orthophosphoric acid or of phosphates are followed by a decrease in the calcium of the serum. Of ten fatal cases, in which the calcium was estimated, the serum contained less than 7 mg. per 100 c.cm. in nine.

Differentiation of Types of Uræmia.

There can be no doubt that the lines of differentiation between the various types of uræmia originally laid down by Volhard[5] still hold good, though recent investigations have added considerably to our knowledge of the chemical changes present. Volhard distinguished true uræmia from the eclamptic pseudo-uræmia which is seen in acute and subacute diffuse nephritis and also in eclampsia. The symptoms which he regarded as typical of true uræmia are, in brief, weakness and wasting, gastro-intestinal disturbances, liability to infection, motor hyperexcitability, and hyperpnœa. The gastro-intestinal symptoms are not infrequently the only sign of the presence of the disease until the terminal stages are reached. Death occurs from cardiac failure after a period of coma of variable duration. True uræmia is frequently a singularly undramatic condition, and is, in many instances, indistinguishable from the so-called latent uræmia which follows bilateral calculus suppression, or cortical necrosis of the kidneys. There is, in fact, no good reason for distinguishing two conditions which clinically and chemically appear to be identical. As Volhard pointed out, an essential feature of the condition is nitrogenous retention, and to this we can now add phosphate retention, diminution in the plasma bicarbonate, and a fall in the calcium content of the serum. The hyperpnœa may reasonably be ascribed to the acidosis which results from phosphate retention; it is continuous and not paroxysmal, resembling the hyperpnœa of diabetic coma. The characteristic localised muscular twitchings or tremor, which are a sign of grave prognostic import, appear to be associated with the diminution in the serum calcium. Theoretically such a diminution should result in increased nervous irritability, and in my own experience those cases in which the calcium fall has been most pronounced have shown this symptom in its most marked form. The blood pressure may be raised, but in a considerable proportion of the patients lies within normal limits; in the present series a case of chronic nephritis, showing a blood-urea content of 561 mg. per 100 c.cm., gave a systolic reading of 124 mm. Hg, while in another patient who gave a history of renal disease of four years' standing, and in whom the blood-urea reached a figure of 269 mg., the systolic blood pressure was 118 mm. Hg. This absence of any correlation between nitrogenous retention and a raised blood pressure is now well recognised, and it has been shown that attempts to raise the blood pressure in the azotæmic type of nephritis by high protein feeding are without result.

The actual cause of death in this type of uræmia remains unknown. The available evidence is against any toxic action of the accumulated nitrogenous waste products, nor has it been satisfactorily proved that the phosphate ion is in itself poisonous to the organism. The effect of the depleted plasma bicarbonate with the resulting tendency to an uncompensated acidosis is uncertain; the administration of sodium bicarbonate and correction of the deficit in the alkaline reserve of the plasma has, however, as in diabetic coma, no definitely beneficial result. It is possible that the ultimate cardiac failure may be associated with the fall in the serum calcium.

In eclamptic pseudo-uræmia, on the other hand, the symptoms are more striking, but the prognosis is relatively good. The most prominent symptoms—headache, vomiting, slow pulse, and generalised convulsions—are apparently of cerebral origin. In some cases temporary amaurosis occurs, and the patient may lapse into coma without preceding convulsions. The symptoms of the condition, whether occurring in connexion with acute nephritis or with true eclampsia, are the same. The chemical examination reveals few abnormalities. The blood is dilute, the percentage of serum solids being considerably less than normal, a condition which is not necessarily present in true uræmia; some degree of chloride and water retention can be shown to be present by balance experiments, and œdema, often slight in degree, is present in all cases. In contra-distinction to true uræmia, the blood-urea content is not appreciably increased, and phosphate retention is absent; the alkaline reserve of the plasma, if estimated before the occurrence of the convulsions, shows no definite diminution. The serum-calcium content, at any rate in cases of true eclampsia, may be at a practically normal level; in six eclamptic patients whom I have had the opportunity of examining the calcium has ranged from 8 to 9·4 mg. per 100 c.cm. of serum. Localised muscular twitchings are absent and the nervous symptoms are cortical rather than peripheral.

The most probable explanation of the chief symptoms of the condition would still appear to be the original suggestion of Volhard, who ascribed the symptoms of pseudo-uræmia to an increased intercranial pressure associated with the raised blood pressure and œdema. On lumbar puncture the intrathecal pressure is abnormally high, the convulsions are frequently preceded by a rise in the blood pressure, and, when once the blood pressure shows a definite fall, no further fits need be anticipated. The chief objection to this theory of pseudo-uræmia lies in the fact that cases of true eclampsia are said to occur without any definite rise in the blood pressure. Further investigation of this point is highly desirable. Briefly, eclamptic pseudo-uræmia is characterised by cerebral symptoms, in association with some degree of retention of water and chlorides and a raised blood pressure; nitrogenous and phosphate retention and the other chemical changes a good response with increase of 14–38 per cent. of hæmoglobin, and were discharged with 64–77 per cent. of hæmoglobin. Improvement was not noted in any case until 3–4 weeks after treatment was begun, and in one case in which the percentage of hæmoglobin increased from 49–71 per cent. in 2¾ months no improvement was noted in the first six weeks of treatment. It is clear, therefore, that to give iron treatment a fair trial one must persist with it for a number of weeks. Of the remaining five cases, three showed an increase of hæmoglobin of 6–10 per cent., and were improving at the time of discharge, and two showed no improvement after 1½–1¾ months' treatment. Several of these five had been handicapped during the period of treatment by other causes. one had an operation for the removal of tonsils and adenoids, one had a pyrexial attack with tonsillitis and otorrhœa, and one was suffering from an X ray burn—the result of a previous unsuccessful attempt to treat the anæmia by radiation of the spleen. If the period of treatment had been longer, there is little doubt that further improvement could have been obtained in the majority of cases. Finkelstein[2] holds that at least three months' treatment should be given in every case, and says that there is no improvement in the hæmoglobin percentage in the first few weeks after the beginning of a course of iron treatment. None of the cases under consideration was treated by a reduction of the quantity of milk in the diet, so that no opinion can be offered as to this method of treatment. But the advocates of strictly dietetic treatment state that the complete change in diet is usually accompanied by a loss of weight, and often results in a refusal of food and a digestive upset (Kleinschmidt[11]), so that if the same object can be attained by the administration of iron without any untoward effects, there is no doubt that the latter would be the treatment to be preferred.

Prophylaxis.

More important than the question of treatment is that of prevention. The evidence available, in the opinion of the author, strongly supports the view that the anæmia is the result, in part at least, of iron starvation, but what other factor or factors play a part in its production is as yet uncertain. Milk contains very little iron; the infant is dependent on the store in its liver, and it has been shown that this store is very low by the end of the normal period of lactation (Bunge[5]). Thus, if the store is used too quickly, the child may well suffer from an insufficiency of iron during the first year of life, and this is likely to happen in an infant fed from an early age on cow's milk on account of the smaller percentage retention of iron in an artificially-fed child.

Attempts to produce anæmia in young animals by giving diets containing insufficient iron have not given consistent results (Kleinschmidt,[11] Hausermann,[12] Schmidt[13]), but have usually resulted in marked anæmia. In view of the recent advances in the technique of dietetic experiments on animals, much of the work of earlier writers appears now of lessened value, but the recent work of Happ[14] on young rats indicates that a diet containing insufficient iron (or for that matter a diet of cow's milk or cow's milk and bread) will not produce anæmia in these animals in the first generation, but that it may occur in the second generation. Possibly, therefore, an insufficiency of iron is only one factor producing "alimentary anæmia" in infants. Nevertheless, if iron starvation plays a part in such anæmias, the question of how the deficiency of iron in the diet is to be supplemented, and from what age this should be done, requires consideration. Finkelstein advocates the administration of fruit juice and vegetables from an early age—to premature infants from 4–5 months of age—but states that such a diet will not necessarily prevent anæmia in premature babies. Kleinschmidt is emphatic that mere supplementing of a milk diet with vegetables without marked reduction in the quantity of milk will not cure the anæmia. Small daily rations of vegetables given to many of the children at the Meidling Hospital from the age of 6 or 7 months did not prevent anæmia, and the giving of eggs to older babies appeared to have no beneficial effect on the amount of hæmoglobin. No evidence was obtained as to whether or not supplementing the milk dietary with any other foodstuff, for instance gravy or meat juice, would have proved prophylactic. In any case, it seems highly desirable that the question of prophylaxis should be further studied, and this the author hopes to have the opportunity of doing in the near future.

Most medical officers in charge of infant welfare centres must have been struck by the number of pale-faced babies attending. What proportion of these are truly anæmic can only be ascertained by examination of the blood, but the number must often be large. No doubt many of these anæmias are not primarily dietetic in origin, but if, as seems probable, one frequent cause is iron starvation, it would appear advisable to administer some form of iron salts as a drug to all such cases at an early stage, whether or not other treatment is given.

Summary.

1. There is a general consensus of opinion that too prolonged and too exclusive a milk dietary produces anæmia in infants and young children. This is probably due in part at least to iron starvation, on account of the low iron content of milk. Some writers, however, have held that it is directly connected with a toxic effect resulting from excessive milk consumption. Premature infants are known to be particularly liable to this form of anæmia.

2. In a group of 36 artificially-fed infants, receiving milk or milk and carbohydrate diets, with or without cod-liver oil, the majority developed anæmia. It was usually noted towards the end of the first year of life, but sometimes appeared as early as the seventh month. Additions of vegetables to the diet from 6 or 7 months old did not prevent anæmia. The infants were in well-lighted and well-ventilated wards, and were much out of doors in summer but very little in winter.

3. Treatment by the administration of inorganic iron salts by mouth brought about improvement in the majority of cases treated, but not in all, possibly because treatment was not continued for a sufficient length of time.

4. No improvement was noted in the hæmoglobin content of the blood in any case within three to four weeks from the beginning of treatment, and improvement might be delayed for six weeks with, thereafter, rapid progress.

5. It is suggested that many cases of anæmia in infants, particularly in those artificially fed from an early age, are probably associated with iron starvation, more especially as it has been experimentally demonstrated that the iron retention of an infant on cow's or goat's milk is much lower than on human milk.

of the French writers and other forms of secondary anæmia, among which they include splenic anæmia of infancy (von Jaksch's anæmia). It is clear, therefore, that opinions have differed greatly as to the cause, symptomatology, and treatment of anæmia occurring in infants given an exclusive milk dietary.

The Normal Blood Count in Infancy.

Different authorities, moreover, are not agreed concerning the normal blood count in infancy, especially with regard to the percentage of hæmoglobin. Holt's figures[13] for infancy represent views commonly held. Exclusive of the first few days of life, they are: Hæmoglobin, 65–85 per cent. ("75 per cent. a low limit in healthy children"); red blood corpuscles, 4–5½ million per c.mm.; white blood corpuscles, 9000–18,000 per c.mm. Finkelstein[2] puts the lower limit of hæmoglobin at 65 per cent.; Kleinschmidt[11] explains the differences of opinion concerning the range of the normal hæmoglobin percentage in infancy as largely due to the differing standard colour tubes used. It would seem that such a figure as 55 per cent. for the lower limit of normal (Aschenheim) must be due to the use of a standard colour tube differing considerably from those used by most workers. Many authorities place the normal red-cell count higher than does Holt—i.e., at 5 million or more per c.mm. (Kleinschmidt[11]).

Personal Observations.

The following observations are published because they demonstrate the extreme frequency of anæmia on cow's milk diets in a group of children living under excellent hygienic conditions. The results came as a surprise to me, and may, perhaps, be of use to others. The observations were made at the Meidling Hospital, Vienna, an institution under the charge of Dr. Egon Rach, and under the direction of Prof. Pirquet, head of the University Kinderklinik. The infants were admitted for an investigation concerned with the prophylaxis and cure of infantile rickets.*

(1) *Diets and Hygienic Condition.*—Two types of diet were in use. One was that in general use in the institution. It consisted of cow's milk with heavy carbohydrate additions. An infant until about 5 months of age was given full milk with the addition of 8·5–20 per cent. of cane sugar. From about 5 months old it received also increasing amounts of cereal, and at about 6 or 7 months small amounts of vegetable purée, usually potato, sometimes carrots or spinach. Fruit purée was usually given at about 8 months, biscuits about 9 months, bread between 9 and 12 months, and butter not till after 12 months. Eggs were given to a few of the older children. The total calorie allowance was high, and the amount of milk consumed daily at 5 months of age was usually over 1 pint. For older infants it was not less than this amount, and was usually nearer 1½ pints.

The other type of diet was a more exclusive milk dietary, so that larger quantities of milk were consumed. It consisted of milk (dried milk was used), with small additions of cod-liver oil. The total calorie allowance was somewhat smaller than in the case of infants on the first type of diet. The quantity of milk was often 1¼–1½ pints at 5 months of age, and older infants occasionally received nearly 2 pints daily for short periods. Before 8–9 months of age little or no added carbohydrate was given. All children on both diets received additional antiscorbutic diet daily, from the time of admission, in the form of orange juice, tomato juice, or swede juice. The infants lived in well-lighted, airy wards. During the summer they were much out of doors, but during the cold Austrian winter they were indoors for weeks at a time.

(2) *Number and General Condition of Infants.*—The records include 36 infants. Twenty-five of the children were admitted under 3 months of age; at the time of the last observation, their age varied from 5½–21 months, 23 being over 9 months. The time in hospital varied from 4½ to 15 months. Three had rickets on admission, and nearly all were under weight at that time, but they were not suffering from acute illnesses. On the whole the level of general health was fairly satisfactory during the period of observation, though there were many minor intercurrent illnesses, such as colds in the head and otorrhœa. Six infants on the first type of diet developed radiographic evidence of rickets in the winter.

(3) *Percentage of Hæmoglobin.*—Approximately 220 hæmoglobin estimations were made with Haldane's hæmoglobinometer from blood collected from a prick in the heel; unfortunately they were not done at regular intervals, as their purpose at first was merely the comparison of infants on the two types of diet. In only three infants of this series was a complete blood count made—in these cases the red count was over 5,000,000 per c.mm. on every occasion, but there was a low hæmoglobin reading of 50 per cent. or less, and consequently a colour index of less than 0·5. The leucocyte count was 12,000–18,000 per c.mm., and the differential count was normal. There was slight polychromatophilia and poikilocytosis. In other words, there was marked anæmia of the so-called "chlorotic type."

Towards the end of the first year of life the majority of cases showed a drop in hæmoglobin, and 23 of the 36 infants had at some time less than 65 per cent. of hæmoglobin. Of 15 infants who were in hospital after 12 months of age, 14 developed a hæmoglobin percentage of 39–65 per cent., and of 23 infants in hospital after 9 months of age, 20 had at some time less than 65 per cent. of hæmoglobin, and 10 less than 55 per cent. Anæmia was generally first noticed between 9 and 12 months of age, but in several cases was well marked (50 per cent. to 60 per cent. of hæmoglobin) between 6 and 9 months of age. In only one child under 6 months of age was the hæmoglobin percentage under 65 per cent. This was a sickly, newly-admitted infant of 2 months, and the hæmoglobin percentage by 5 months of age had risen, with improvement in the general health, to 82 per cent.

These figures indicate that nearly all infants fed on the types of diet described developed anæmia at the end of the first year of life, in spite of good hygienic conditions and in many cases in spite of good general health. A number of infants, notwithstanding the low hæmoglobin content of their blood and their striking pallor, appeared to feel remarkably well and were extremely active. From the numbers observed there was no evidence that anæmia was more marked among infants on one type of diet than among those on the other, although one group of infants received cereal and vegetable additions to their dietary earlier than the other group. Possibly a larger number of cases might have revealed some difference. Eggs (½–1 daily), given for 3 to 5 months to a few infants, appeared to exercise no influence on the degree of the anæmia. Nor was the anæmia particularly associated with rickets; some cases who developed slight rickets had no anæmia, and in a case with no clinical or radiographic evidence of rickets the hæmoglobin fell as low as 39 per cent. There was no clear association between anæmia and so-called exudative diathesis (cf. Kleinschmidt[11]), nor with splenic enlargement. Only one of these cases had a definitely enlarged spleen, and in that case the degree of anæmia was slight. Cases with anæmia showed no tendency towards spontaneous recovery. There was in winter a progressive fall in the amount of hæmoglobin after the condition had developed. Outdoor life and summer conditions, with the resultant improvement in general health, did not bring about improvement in the blood condition in a single case in which anæmia had occurred, but in some cases the condition seemed to have been arrested.

(4) *Treatment.*—The form of treatment given was the administration of iron salts by mouth. The preparation used was ferri carb. sacch., 4½–9 gr. daily. The doses were given in the food and caused no digestive disturbance. Twelve infants received this treatment for from 1½–3 months, and seven showed

---

a good response with increase of 14–38 per cent. of hæmoglobin, and were discharged with 64–77 per cent. of *hæmoglobin*. Improvement was not noted in any case until 3–4 weeks after treatment was begun, and in one case in which the percentage of hæmoglobin increased from 49–71 per cent. in 2¾ months no improvement was noted in the first six weeks of treatment. It is clear, therefore, that to give iron treatment a fair trial one must persist with it for a number of weeks. Of the remaining five cases, three showed an increase of hæmoglobin of 6–10 per cent., and were improving at the time of discharge, and two showed no improvement after 1¼–1¾ months' treatment. Several of these five had been handicapped during the period of treatment by other causes, one had an operation for the removal of tonsils and adenoids, one had a pyrexial attack with tonsillitis and otorrhœa, and one was suffering from an X ray burn—the result of a previous unsuccessful attempt to treat the anæmia by radiation of the spleen. If the period of treatment had been longer, there is little doubt that further improvement could have been obtained in the majority of cases. Finkelstein[2] holds that at least three months' treatment should be given in every case, and says that there is no improvement in the hæmoglobin percentage in the first few weeks after the beginning of a course of iron treatment. None of the cases under consideration was treated by a reduction of the quantity of milk in the diet, so that no opinion can be offered as to this method of treatment. But the advocates of strictly dietetic treatment state that the complete change in diet is usually accompanied by a loss of weight, and often results in a refusal of food and a digestive upset (Kleinschmidt[11]), so that if the same object can be attained by the administration of iron without any untoward effects, there is no doubt that the latter would be the treatment to be preferred.

Prophylaxis.

More important than the question of treatment is that of prevention. The evidence available, in the opinion of the author, strongly supports the view that the anæmia is the result, in part at least, of iron starvation, but what other factor or factors play a part in its production is as yet uncertain. Milk contains very little iron; the infant is dependent on the store in its liver, and it has been shown that this store is very low by the end of the normal period of lactation (Bunge[5]). Thus, if the store is used too quickly, the child may well suffer from an insufficiency of iron during the first year of life, and this is likely to happen in an infant fed from an early age on cow's milk on account of the smaller percentage retention of iron in an artificially-fed child.

Attempts to produce anæmia in young animals by giving diets containing insufficient iron have not given consistent results (Kleinschmidt,[11] Hausermann,[14] Schmidt[15]), but have usually resulted in marked anæmia. In view of the recent advances in the technique of dietetic experiments on animals, much of the work of earlier writers appears now of lessened value, but the recent work of Happ[16] on young rats indicates that a diet containing insufficient iron (or for that matter a diet of cow's milk or cow's milk and bread) will not produce anæmia in these animals in the first generation, but that it may occur in the second generation. Possibly, therefore, an insufficiency of iron is only one factor producing "alimentary anæmia" in infants. Nevertheless, if iron starvation plays a part in such anæmias, the question of how the deficiency of iron in the diet is to be supplemented, and from what age this should be done, requires consideration. Finkelstein advocates the administration of fruit juice and vegetables from an early age—to premature infants from 4–5 months of age—but states that such a diet will not necessarily prevent anæmia in premature babies. Kleinschmidt is emphatic that mere supplementing of a milk diet with vegetables without marked reduction in the quantity of milk will not cure the anæmia. Small daily rations of vegetables given to many of the children at the Meidling Hospital from the age of 6 or 7 months did not prevent anæmia, and the giving of eggs to older babies appeared to have no beneficial effect on the amount of hæmoglobin. No evidence was obtained as to whether or not supplementing the milk dietary with any other foodstuff, for instance gravy or meat juice, would have proved prophylactic. In any case, it seems highly desirable that the question of prophylaxis should be further studied, and this the author hopes to have the opportunity of doing in the near future.

Most medical officers in charge of infant welfare centres must have been struck by the number of pale-faced babies attending. What proportion of these are truly anæmic can only be ascertained by examination of the blood, but the number must often be large. No doubt many of these anæmias are not primarily dietetic in origin, but if, as seems probable, one frequent cause is iron starvation, it would appear advisable to administer some form of iron salts as a drug to all such cases at an early stage, whether or not other treatment is given.

Summary.

1. There is a general consensus of opinion that too prolonged and too exclusive a milk dietary produces anæmia in infants and young children. This is probably due in part at least to iron starvation, on account of the low iron content of milk. Some writers, however, have held that it is directly connected with a toxic effect resulting from excessive milk consumption. Premature infants are known to be particularly liable to this form of anæmia.

2. In a group of 36 artificially-fed infants, receiving milk or milk and carbohydrate diets, with or without cod-liver oil, the majority developed anæmia. It was usually noted towards the end of the first year of life, but sometimes appeared as early as the seventh month. Additions of vegetables to the diet from 6 or 7 months old did not prevent anæmia. The infants were in well-lighted and well-ventilated wards, and were much out of doors in summer but very little in winter.

3. Treatment by the administration of inorganic iron salts by mouth brought about improvement in the majority of cases treated, but not in all, possibly because treatment was not continued for a sufficient length of time.

4. No improvement was noted in the hæmoglobin content of the blood in any case within three to four weeks from the beginning of treatment, and improvement might be delayed for six weeks with, thereafter, rapid progress.

5. It is suggested that many cases of anæmia in infants, particularly in those artificially fed from an early age, are probably associated with iron starvation, more especially as it has been experimentally demonstrated that the iron retention of an infant on cow's or goat's milk is much lower than on human milk.

Reviews and Notices of Books.

A TEXT-BOOK OF THERAPEUTICS.

Including the Essentials of Pharmacology and Materia Medica. Sixth edition. By A. A. STEVENS, A.M., M.D., Professor of Applied Therapeutics in the University of Pennsylvania, Philadelphia; Visiting Physician to the University and the Philadelphia General Hospitals. London and Philadelphia: W. B. Saunders Company. 1923. Pp. 793. 30*s*.

THIS book is one which deserves to be better known in this country amongst students who have attained to house appointments and amongst all actively engaged in the practice of medicine. Of the books on treatment at present available which are at once comprehensive, up-to-date, and discriminating, it is one of the best we have met. It is divided into two parts, of which the first deals with the various therapeutic agents, their pharmacological action and method of application; the second part, occupying the last 250 pages, is a compact survey of the treatment of most acute and chronic diseases. A prominent feature is the inclusion of numerous prescriptions and a discussion of incompatible substances. In addition to the various pharmacopœial preparations mentioned, useful attention is given to a consideration of the better known proprietary preparations. The chief merit of the book, however, lies in its exposition of modern methods. There is a good account of C. Eggleston's views on the value of administering large doses of digitalis, and of the indications for and against the use of quinidine in heart disease; of Schleich's method of infiltration anæsthesia with local anæsthetics; of the Schick test and of Park's results with toxin-antitoxin mixtures in immunisation against diphtheria; of the treatment of amœbic dysentery with emetine-bismuth-iodide by the mouth; of Chandler Walker's method of treating bronchial asthma with specific proteins; of the Allen treatment of diabetes, which includes a table giving the protein, fat, and carbohydrate percentages in ordinary foods; of the Sippy treatment of gastric ulcer. Chapters, written with judgment and restraint, are devoted to electrical treatment, massage, the Nauheim treatment for chronic heart disease, X ray and radium therapy and the Finsen-light treatment. Turkish and Russian baths, hot packs, hypodermoclysis and gastric lavage are discussed.

A book of this kind should obviously be of great value, presenting as it does within one volume a critical account of so many matters otherwise only available in scattered papers.

There is surprisingly little to which exception can be taken. There is no mention of the treatment of tuberculosis by heliotherapy in climates where the high cooling power of the air makes prolonged exposure to sunlight possible; indeed, Prof. Stevens thinks that sanatorium treatment has been shown to be equally successful in all climates. The work done in this country during the war on the treatment of shock has hardly received adequate attention. While Bayliss's gum-saline is described in the chapter on infusion and hypodermoclysis, the author has nothing better to advise for shock than adrenalin and pituitary extract. Unless A. Krogh's recent work on the frog is to be taken as such an indication, there is as yet no evidence whatever that pituitary extract is of the slightest value in shock treatment; the defect is one of the capillary circulation which pituitary extract does not influence. Perhaps a more serious error occurs in reference to the use of pituitary extract in labour. Prof. Stevens states that when the os is fully dilated, in cases of uterine inertia, 0·5 c.cm. of pituitary extract may be given. It is not sufficiently realised how potent this remedy is, and text-book statements of this kind, if followed up, are bound to produce the opinion that the extract is dangerous; for such a dose is two or three times too great. Doses of from 0·1 c.cm. to 0·2 c.cm. of the ordinary 10 per cent. extract are amply sufficient for administration in the second or first stage; ignorance of this important point has led many conscientious obstetricians to neglect the valuable aid pituitary extract can give.

A dozen such criticisms, however, leave the main excellence of the book unimpaired; such points are inevitable when the net is cast so wide. The author is to be congratulated on having on so many sides and with so much judgment succeeded in presenting such an excellent work in the limits of one volume.

MULTIPLE SCLEROSIS (DISSEMINATED SCLEROSIS).

Being Vol. II. of the Series of Investigations and Reports of the *Association for Research in Nervous and Mental Diseases*. New York: Paul B. Hoeber. 1922. Pp. 241. $3.75.

IF the report on disseminated sclerosis by numerous distinguished American investigators does not yet solve the problem of the disease, it brings us somewhat nearer that desirable end. The reader familiar with the subject naturally turns to the sections dealing with the nature and ætiology of the affection, only to find that the Commission declares it extremely difficult to decide whether the disease is inflammatory or degenerative; in fact, they admit frankly they have not reached a conclusion on the question of the existence of *acute multiple sclerosis as distinct from* encephalitis or lues. They cannot regard the problem of a possible micro-organismal origin as either confirmed or unsubstantiated on histological grounds. It might appear as if we are farther off than ever from the solution of a common and widespread organic nervous disease. What is of value in this report, however, is the collation of an immense amount of data in reference to the geographical distribution, incidence, frequency, racial apportionment, and general ætiological factors of multiple sclerosis; the setting of the problem, we may say, is rendered more distinct thereby. The chapter on general and special symptomatology apparently omits any reference to the interesting group in which epilepsy is an early, sometimes the very first, symptom of the disease. There is an excellent bibliography, but the volume is sorely in need of an index.

THE COMMON NEUROSES: THEIR TREATMENT BY PSYCHOTHERAPY.

By T. A. ROSS, M.D., F.R.C.P.E., Medical Director, Cassel Hospital for Functional Nervous Disorders. London: Edward Arnold and Co. 1923. Pp. 256. 12*s*. 6*d*.

DR. ROSS opens by a survey of the many fashions that have come and gone in the theories and treatment of the neuroses—the exhaustion theory, with its rest cure, the "reflex" theory with treatment directed to the uterus, to minor refractive errors, to "dropped kidneys," nasal spurs and deflections or to "dropped kidneys," and the still current toxic theory—and decides that enthusiastic if short-lived belief was the agent that removed symptoms. Drawing almost entirely upon his own experiences, of which 17 years were spent in general practice—a source of ample material for the study of neuroses—he demonstrates the psychogenic nature of these conditions and provides copious illustrations of his methods of treating them. He relies upon analysis, explanation, and persuasion combined or as alternatives, and the frank accounts of his own difficulties and failures, together with a restrained tone throughout the book, are a welcome contrast to those optimistic writings upon psychotherapy which raise the suspicion that here, too, we may have only another phase of enthusiastic belief. His attitude towards psycho-analysis is not well defined. In the preface he takes the view, scarcely justified by a retrospective glance, that ten years ago the spell of Freud was so potent that the writings of Dejerine were unduly handicapped. Giving full credit to Freud's work and making free use of his methods, he employs the strange phrase, concerning the taking of a history, that " there is no taint of psycho-analysis about it " (p. 112). It is perhaps fear of this taint that makes him skim lightly over difficult problems. Sexual impotence, for example, cannot always be removed by reassurance, and the marriage of an impotent man, which he would allow (p. 110), is often followed by unhappy results; sexual frigidity in women, an equally potent source of unhappiness, or worse, is not mentioned. Dr. Ross's handling of the compulsion neurosis is weak, in both the treatment and the symptomatology of this important and often unrecognised condition. He shares the view, which possibly had origin in a mis-translation in an American edition of Freud's " Introductory Lectures," that analysis is contra-indicated in this neurosis, and describes his own failure in a patient of 49, who was " physically and psychologically a rather old man " ; few psycho-analysts would have attempted the task in a patient of that age and type, but analysts claim most satisfactory results in properly selected obsessional cases, and Dr. Ross, in quoting Jelliffe, gives the unfortunate impression that the gloomy prognosis is orthodox.

These weak points, however, detract but little from the usefulness of the book to the general practitioner, for whom it is written and to whom it may be cordially recommended.

MEDICAL DIAGNOSIS.

Fifth edition. By CHARLES LYMAN GREENE, M.D., formerly Professor of Medicine, University of Minnesota and Chief of Medical Clinic in the University Hospitals. London: William Heinemann. 1922. Pp. 1453. 63s.

THE new edition of this work contains 75 new illustrations and an additional 150 pages. More than half of the new matter is included in the section dealing with disorders of the heart and blood-vessels to which Prof. Green devotes particular attention, the many facsimiles of electro-cardiograms being very valuable. We doubt whether all readers will agree with his remarks on " drop heart," and feel that auricular flutter should be included in the classified list of arrhythmias on p. 543, but otherwise we find this section illuminating. The vast amount of information in the book is made readily accessible by the excellence of the indices as well as by the provision on each page of a margin containing terse epitomes. The author's descriptions of the latest tests and aids to diagnosis, and his reasoned and moderate view of their individual value enhance the value of the work which, if too comprehensive for students, forms an excellent text-book of diagnosis.

CYSTOSCOPY AND URETERIC CATHETERISATION.

Traité pratique de cystoscopie et de cathétérisme urétéral. Second edition. By G. MARION, Professeur agrégé à la Faculté, Chirurgien de l'Hôpital Lariboisière (service civile); and M. HEITZ-BOYER, Professeur agrégé des voies urinaires à la Faculté, Chirurgien de l'Hôpital Saint-[illegible] Paris: Masson et Cie. 1923. Pp. [illegible]

IN the second edition of their book on Cystoscopy MM. Marion and Heitz-Boyer have not changed the general arrangement of the work. They have, however, entirely rewritten the chapter d[illegible] the optical principles involved and [illegible] pretation of images; and they have now given less space to the discussion of direct and indirect (or reversed) images, for as they justly remark, urinary surgeons should be equally conversant with both methods. One chapter is new and deals with urethrocystoscopy as first described by Buerger. Many additions have been made in the chapters on pyelography, the estimation of renal efficiency, and cystoscopic operations. It is of interest to note that these surgeons prefer the high-frequency spark to the diathermy current as employed in this country, believing that the former is more exact and more easily controlled.

The second edition should appeal to an even larger number of the profession than the first. It is admirably written, and has the advantage of being based on the personal experiences of two well-known genito-urinary surgeons. It contains in all 60 plates, mostly in colours, of cystoscopic findings, described in no less than five languages.

SELECTED PAPERS AND ADDRESSES.

By WILLIAM WILLIAMS KEEN, M.D., LL.D., Emeritus Professor of Surgery, Jefferson Medical College of Philadelphia. Philadelphia: George W. Jacobs and Co. 1923. Pp. 340.

Prof. Keen is well known on this side of the Atlantic as the doyen of surgery in the United States, and his book shows that he can write lucid and literary English with something of that indefinable quality which pervades the writing of John Brown of the " Horæ Subsecivæ." The papers and addresses were written at various times and upon different occasions, and therefore, as Prof. Keen implies in his preface, are not necessarily to be taken as setting forth the present-day opinions of their author. Some of them, however, deal with matters which are as permanent as anything can be in this world of flux, as, for instance, the paper upon the conditions of surgery before and after Lister: that upon the benefits not only to human beings, but also to the lower animals derived from experiments upon animals; and that entitled " Things Surgeons Stand For."

Other papers deal with the Service of Missions and with the impossibility of a war between Great Britain and the United States. Altogether the collection is a satisfying one which should be read and pondered not only by medical men, but by all who have the welfare of humanity at heart.

GENERALISED PAIN.

Being Part II. of the Clinical Symptomatology of Internal Diseases. By Prof. Dr. NORBERT ORTNER, Vienna. Authorised translation by FRANCIS J. RIEMAN. With an introduction by THOMAS WEBSTER EDGAR, M.D., New York. New York Medical Art Agency. 1922. Pp. 596.

To analyse and describe all the varieties and causes of pain in the body, literally, from scalp to [illegible] an ambitious project; to carry it out with any [illegible] of success is matter for congratulation. We [illegible] Prof. Ortner has reason to pride himself on [illegible] [illegible] for only a physician w[illegible] [illegible] specialties can [illegible] [illegible] in anything like [illegible] [illegible] heart, back [illegible] [illegible] bones, joints [illegible] [illegible]

Reviews and Notices of Books.

A Text-Book of Therapeutics.

Including the Essentials of Pharmacology and Materia Medica. Sixth edition. By A. A. Stevens, A.M., M.D., Professor of Applied Therapeutics in the University of Pennsylvania, Philadelphia; Visiting Physician to the University and the Philadelphia General Hospitals. London and Philadelphia: W. B. Saunders Company. 1923. Pp. 793. 30*s*.

This book is one which deserves to be better known in this country amongst students who have attained to house appointments and amongst all actively engaged in the practice of medicine. Of the books on treatment at present available which are at once comprehensive, up-to-date, and discriminating, it is one of the best we have met. It is divided into two parts, of which the first deals with the various therapeutic agents, their pharmacological action and method of application; the second part, occupying the last 250 pages, is a compact survey of the treatment of most acute and chronic diseases. A prominent feature is the inclusion of numerous prescriptions and a discussion of incompatible substances. In addition to the various pharmacopœial preparations mentioned, useful attention is given to a consideration of the better known proprietary preparations. The chief merit of the book, however, lies in its exposition of modern methods. There is a good account of C. Eggleston's views on the value of administering large doses of digitalis, and of the indications for and against the use of quinidine in heart disease; of Schleich's method of infiltration anæsthesia with local anæsthetics; of the Schick test and of Park's results with toxin-antitoxin mixtures in immunisation against diphtheria; of the treatment of amœbic dysentery with emetine-bismuth-iodide by the mouth; of Chandler Walker's method of treating bronchial asthma with specific proteins; of the Allen treatment of diabetes, which includes a table giving the protein, fat, and carbohydrate percentages in ordinary foods; of the Sippy treatment of gastric ulcer. Chapters, written with judgment and restraint, are devoted to electrical treatment, massage, the Nauheim treatment for chronic heart disease, X ray and radium therapy and the Finsen-light treatment. Turkish and Russian baths, hot packs, hypodermoclysis and gastric lavage are discussed.

A book of this kind should obviously be of great value, presenting as it does within one volume a critical account of so many matters otherwise only available in scattered papers.

There is surprisingly little to which exception can be taken. There is no mention of the treatment of tuberculosis by heliotherapy in climates where the high cooling power of the air makes prolonged exposure to sunlight possible; indeed, Prof. Stevens thinks that sanatorium treatment has been shown to be equally successful in all climates. The work done in this country during the war on the treatment of shock has hardly received adequate attention. While Bayliss's gum-saline is described in the chapter on infusion and hypodermoclysis, the author has nothing better to advise for shock than adrenalin and pituitary extract. Unless A. Krogh's recent work on the frog is to be taken as such an indication, there is as yet no evidence whatever that pituitary extract is of the slightest value in shock treatment; the defect is one of the capillary circulation which pituitary extract does not influence. Perhaps a more serious error occurs in reference to the use of pituitary extract in labour. Prof. Stevens states that when the os is fully dilated, in cases of uterine inertia, 0·5 c.cm. of pituitary extract may be given. It is not sufficiently realised how potent this remedy is, and text-book statements of this kind, if followed up, are bound to produce the opinion that the extract is dangerous: for such a dose is two or three times too great. Doses of from 0·1 c.cm. to 0·2 c.cm. of the ordinary 10 per cent. extract are amply sufficient for administration in the second or first stage; ignorance of this important point has led many conscientious obstetricians to neglect the valuable aid pituitary extract can give.

A dozen such criticisms, however, leave the main excellence of the book unimpaired; such points are inevitable when the net is cast so wide. The author is to be congratulated on having on so many sides and with so much judgment succeeded in presenting such an excellent work in the limits of one volume.

Multiple Sclerosis (Disseminated Sclerosis).

Being Vol. II. of the Series of Investigations and Reports of the Association for Research in Nervous and Mental Diseases. New York: Paul B. Hoeber. 1922. Pp. 241. $3.75.

If the report on disseminated sclerosis by numerous distinguished American investigators does not yet solve the problem of the disease, it brings us somewhat nearer that desirable end. The reader familiar with the subject naturally turns to the sections dealing with the nature and ætiology of the affection, only to find that the Commission declares it extremely difficult to decide whether the disease is inflammatory or degenerative; in fact, they admit frankly they have not reached a conclusion on the question of the existence of acute multiple sclerosis as distinct from encephalitis or lues. They cannot regard the problem of a possible micro-organismal origin as either confirmed or unsubstantiated on histological grounds. It might appear as if we are farther off than ever from the solution of a common and widespread organic nervous disease. What is of value in this report, however, is the collation of an immense amount of data in reference to the geographical distribution, incidence, frequency, racial apportionment, and general ætiological factors of multiple sclerosis; the setting of the problem, we may say, is rendered more distinct thereby. The chapter on general and special symptomatology apparently omits any reference to the interesting group in which epilepsy is an early, sometimes the very first, symptom of the disease. There is an excellent bibliography, but the volume is sorely in need of an index.

The Common Neuroses: Their Treatment by Psychotherapy.

By T. A. Ross, M.D., F.R.C.P.E., Medical Director, Cassel Hospital for Functional Nervous Disorders. London: Edward Arnold and Co. 1923. Pp. 256. 12*s*. 6*d*.

Dr. Ross opens by a survey of the many fashions that have come and gone in the theories and treatment of the neuroses—the exhaustion theory, with its rest cure, the "reflex" theory with treatment directed to the uterus, to minor refractive errors, to nasal spurs and deflections or to "dropped kidneys," and the still current toxic theory—and decides that enthusiastic if short-lived belief was the agent that removed symptoms. Drawing almost entirely upon his own experiences, of which 17 years were spent in general practice—a source of ample material for the study of neuroses—he demonstrates the psychogenic nature of these conditions and provides copious illustrations of his methods of treating them. He relies upon analysis, explanation, and persuasion

SIXTH CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY.

(Concluded from p. 147.)

WEDNESDAY, JULY 18TH.

Arthroplasty.

Mr. E. W. Hey Groves (Bristol) defined arthroplasty as an operative procedure upon an ankylosed joint with the object of restoring mobility. The pseudo-arthrosis occasionally resulting from an ununited fracture proved that the formation of a new joint with adapted articular surfaces and a capsule and synovia was within the powers of nature, yet the results of attempts to form a new joint by operation were variable and not always successful. Mobilisation of the elbow by some form of operation was usually successful, while arthroplasty of the hip and knee was frequently disappointing. The conditions most favourable to arthroplasty were bony ankylosis due to trauma or long cured pyæmia and occasional cases of osteo-arthritis and tubercle. The essential operative procedure in arthroplasty was the making of a gap between the articular ends, which gap must be maintained until healing took place; shaping and covering the articular ends was useful but not essential. Continuous traction on the new articulation and early voluntary movement were most necessary in after-treatment. In the elbow the suitable cases were those of bony ankylosis free from active infection, except those in which a strong useful arm was present in a labouring man. He considered that the best operation for the elbow was to preserve the whole width of the humeral condyles and to cover this bone with a free flap of fascia lata. In the hip there were three different types of operation to be considered: (1) For simple ankylosis an osteotomy of the neck of the femur with interposition of a flap taken from the fascia or from the capsule; (2) for massive hypertrophic ankylosis, a subtrochanteric osteotomy with the interposition of a fascial flap, forming a saddle-shaped joint; (3) for osteo-arthritis, excision of the head of the femur. In the knee any operation was unjustified if the joint were fixed in a good position, and it was only in the case of ankylosis of both knees that arthroplasty should be considered. The essential points in any such operation were the use of free fascia to cover the lower end of the femur, the preservation of the lateral ligaments, and the use of a jointed knee-cage for some months afterwards. If lateral mobility persisted, then the lateral ligaments must be reinforced by a second operation.

Prof. V. Putti (Bologna) gave his experiences gathered from 142 arthroplasties, the first of which was performed 10 years ago. He pointed out that arthroplasty was a severe and traumatising operation, and depended much for its success upon the coöperation of the patient in the after-treatment. It should therefore be reserved for patients of good vitality between 20 and 50 years of age, whose mental condition was good in that they were neither hypersensitive nor neuropathic. The profession of the patient was also important: in certain callings strength was preferable to movement. Bony ankylosis gave better results than fibrous: the ankylosis following acute infective arthritis (especially when the result of war wounds), polyarticular arthritis and certain cases of osteo-arthritis of the hip, and, rarely, of tuberculous arthritis were indications for arthroplasty. Operation should not be performed until after the lapse of a year from the time of the last acute manifestations. Ankylosis of the temporo-maxillary joint, bilateral ankylosis of the hip-joints, and ankylosis of the elbow in extension were all absolute indications. In the knee equally good results could be obtained as in the elbow. The operation consisted essentially of the partial resection of the joint which should be neither too extensive nor too sparing, and the exact fitting of the articular surfaces by means of gouges and files. The raw bony surfaces were then covered by free flaps of fascia lata, sewn into position, and the joint reconstructed by careful suture of the muscles, &c. Extension was kept upon the joint after the operation, and free use was made of active hyperæmia induced by radiant heat. Movements were begun by the patient in 12 to 15 days. After arthroplasty of the lower limb the patient should be able to walk within a month. The new joint was gradually and slowly developed as the result of use; the action of the flaps of fascia lata was merely temporary, but they were very helpful in the early stages. He had occasionally found it necessary to open one of these new joints some years after arthroplasty, when he found a condition strongly resembling the normal articulation. Movement was painless, and tended to increase with time rather than to decrease; the new joints were not affected by osteo-arthritis, but remained functionally good after many years of use. After delivering his report Prof. Putti showed cinematographic records of arthroplasty of the knee, showing all the details of the operation, the after-treatment, and the results. He concluded by exhibiting four cases in whom he had performed arthroplasty of the knee for bony ankylosis following war injuries. All four had a range of at least 90° of flexion from full extension (without undue lateral movement) and walked normally; it is worthy of remark that all were still serving in the Italian Army and doing full duty, two of them as officers.

Dr. W. R. MacAusland (Boston, U.S.A.) discussed the present position of arthroplasty, and pointed out in what respects it differed from mobilising excision. After a brief reference to the pioneer work of Baer, who used chromicised pig's bladder for interposition, and of the late J. B. Murphy, who developed the use of a pedunculated fat flap for the same purpose, he described the use of free fascia lata flaps after the method of Putti and Peyr, which had given the most uniformly successful results. Dr. MacAusland's report was lavishly illustrated with drawings and photographs, showing the technique and results of arthroplasty in the various joints in which he had found the operation of arthroplasty useful, notably the elbow-, hip-, and knee-joints, and cinematograph pictures were shown at the meeting of the operation of arthroplasty upon the elbow-joint. Access was gained to the joint by severing the olecranon process, and the remaining details of the operation resembled those of Prof. Putti's arthroplasty of the knee, except that only one bony surface (that of the humerus) was covered by the fascia lata flap. As a result of the operation, about 100° of movement could be obtained: in the earlier cases this was from full extension, but more recently he aimed at a range of from 45° to 145° (full extension = 180°), which he considered more useful. In considering the indications for arthroplasty, the speaker agreed broadly with those who preceded him, but he laid special emphasis upon the necessity for reserving arthroplasty for joints in which the muscles were still in good condition. The joints which gave the best results were the elbow, hip, and knee.

Dr. P. Santy's (Lyons) contribution was read by Dr. R. Leriche. Dr. Santy said that surgical mobilisation of ankylosed joints had so far been little used in France, probably because they continued to use Ollier's mobilising resection in certain cases. In the shoulder, elbow, and wrist Ollier's technique gave excellent results, but to obtain them great tenacity and patience was required, not only of the surgeon, but also of the patient during the weeks of mobilisation, while the articulation adapted itself to the neoarthrosis. Arthroplasty was, however, undoubtedly an improvement in technique, and hastened results. For the hip, mobilising resection was sometimes indicated, for example, in the case of large bony fusions where surgical modelling and interposition was difficult. Apart from these cases, arthroplasty was again an advance in treatment.

phenomenon in tabes," "motoric aphesia," &c.), we regret that the author's meaning should thus suffer in careless translation: "diseases of the brain occupy the area of the trigeminal nerve which is the original habitat of paræsthesias" (p. 281); "I do not refer to the sensible aura of epilepsy" (p. 330); "bitemporal contraction of the face (hemianopsia)" (p 287), &c. The English rendering becomes ridiculous when we are told that varicose veins cause "edema of the knuckle." Many unfamiliar expressions—"Wolhynian fever," "Sudek's atrophy," "Pappataci fever," "malum Rustii," "Bruck's disease," "Jack's disease" (can this be von Jaksch's disease?), "pyrgocephalus," &c. occur. For those, however, to whom the original is not accessible even an indifferent translation will be acceptable.

SURGICAL DIAGNOSIS.

Exploration clinique et diagnostic chirurgical. By Felix Lejars, Professeur de Clinique Chirurgicale à la Faculté de Médecine de Paris; Chirurgien de l'Hôpital Saint-Antoine; Ancien Président de la Société de Chirurgie. Paris: Masson et Cie. 1923. Pp. 778. Fr.60.

It is a charge frequently levelled at the present generation that its powers of diagnosis are vastly inferior to those of its forefathers. The charge can be easily answered, but no one denies that there exists room for improvement in this most difficult department of medical science. None will gainsay the existence of "clinical instinct," but this does not imply that diagnostic ability may not be acquired. How then may it be taught? We believe that an exhaustive, exact, and intelligent examination of the patient, combined with a judicial review of the history, will enable the student often to make accurate diagnoses, without having continual resort to multiple laboratory tests. It is for this reason that we welcome this book.

Prof. Lejars has set himself to describe a precise technique for the examination of every kind of pathological condition in every part of the body. He has succeeded in so doing in a concise manner, and has been aided in making his meaning easily understood by a very large number of illustrations. The style in which the book is written may not appeal to some in this country, and the reproductions of the X ray photographs are in most cases poor, but there can be no doubt that it is a book of great value and should appeal to a wide circle.

THE EVOLUTION OF MAN.

A Series of Lectures delivered before the Yale Chapter of the Sigma Xi during the Academic Year 1921–22. Edited by George Alfred Baitsell. London: Humphry Milford, Oxford University Press; New Haven: Yale University Press. 1923. Pp. 202. 15*s.*

There are six lectures included in this book, with a bibliography and index. The subjects of the lectures are the Antiquity of Man, the Natural History of Man, the Evolution of the Nervous System of Man, the Evolution of Intelligence, Societal Evolution, and the Trend of Evolution. The authoritative nature of the statements made is assured from the names of the collaborators, Profs. R. S. Lull, H. B. Ferris, G. H. Parker, A. G. Keller, E. G. Conklin, and President J. R. Angell. It is evident that the book is not intended for specialists in the various departments with which it deals, but rather for those others who desire acquaintance with what is being thought and said in the biological world and laboratories. We have read the book with very great pleasure, for the lectures are not only authoritative but are phrased in clear and simple language. The earlier lectures are clearly illustrated. We can heartily recommend this work to the medical man who has little time to spare but wishes to know how matters evolutionary stand to-day. The volume is handy and well produced.

SURGICAL ANATOMY OF EMERGENCY OPERATIONS.

Topographische Anatomie dringlicher Operationen. Second edition. By J. Tandler. Berlin: Julius Springer. 1923. Pp. 118. 8*s.* 4*d.*

In this book the surgical anatomy of emergency operations is considered and the steps of each procedure set forth. The descriptions are clear and the many very beautiful illustrations self-explanatory. In a book devoted to anatomy only one naturally looks for an account of variations in the typical relations of the structures in the gastro-hepatic omentum, a subject of great importance to the surgeon. But this does not appear, probably because the author is an anatomist and not a surgeon. The latter gets the impression at operations that the cystic artery rather more commonly passes behind than in front of the common bile-duct, as depicted on p. 67. By a printer's error, the structures shown in Fig. 54 have been wrongly labelled. The oblique lumbar incision for exposing the kidney is described, but when, in an emergency, a bilateral nephrotomy or decapsulation has to be performed, the Mayo approach, which is not mentioned, is simpler and quicker.

VISCEROPTOSIS.

Les désanglés du ventre; Maladies par relâchement des parois et organes abdominaux. By Dr. Chauvois. Paris: A. Maloine et Fils. 1923. Pp. 167.

In this little book Dr. Chauvois described the varieties and results of atony of the abdominal wall, with its effects on the abdominal viscera. The illustrations are an important part of the work, being for the most part arranged in pairs to show the clinical types under discussion side by side with types of healthy and well-built subjects. Full recognition is given to the writings of Glènard, and the author has made no attempt to cover every aspect of his subject; technicalities are avoided, for Dr. Chauvois appeals not only to medical men, but also to lay people, and especially parents. With this object, in the chapters on treatment the greatest prominence is given to the early stages of the disability and to its prevention, particularly in childhood. Methods of general hygiene, and the value of correct abdominal supports, fresh air, baths, athletics, and special breathing and gymnastic exercises are described. In England we have been rather in advance of France in these matters, but abdominal atony is only too common, and this book is of considerable educational value; its main practical defect is that insufficient attention is directed to the importance of looking for and eradicating any focus of sepsis, in children especially, for this is the primary cause of the lethargic habit in very many cases.

SURGERY.

Grundriss der gesamten Chirurgie. Second edition. By Prof. Dr. Erich Sonntag, Vorstand des Chirurgisch-poliklinischen Instituts der Universität, Leipzig. Berlin: Julius Springer. 1923. Pp. 937. 11*s.* 8*d.*

This book is written in the form of a synopsis of general surgery. It is well arranged and classified under suitable headings for the various systems, and could be used by students as a "crammer" for revision before examinations, or by the practitioner for reference in times of emergency. To literary style it makes no pretence, and it confines itself to the orthodox teaching of the day, without attempting to present or to solve any of the numerous controversies with which modern surgery abounds. The book includes a short chapter on operative surgery, which, while necessary for the completion of the work, is almost too short and sketchy to be of much practical value, more especially as it lacks illustrations. The fact that a second edition has appeared is sufficient evidence that the book is in demand and fills a definite place in the literature of its kind.

tissue. When the nerve was bruised, it seemed best to preserve it and keep it under constant observation. When some time had elapsed before the patient had received medical attention, the lesion should be operated on as quickly as possible. Aseptic operation, however, was essential, and it might be necessary to wait some weeks until all signs of suppuration had disappeared. As regards the operation to be done, Prof. Gosset thought that in the case of nerve compression with signs of irritation, simple liberation was all that was necessary. Intra-nervous extraneous bodies should always be taken out, but small intrafascicular fibromata should be enucleated only when the operation was without danger to the healthy nerve bundles. If there were interruption in the continuity of the nerve which showed no improvement after several examinations, resection of the fibrous callus and suture of the neurilemma should be undertaken. If suture were impossible, a graft, or the dividing into two of the lower end, should be practised. Good results would only be obtained if the patient had been kept free from ankylosis and muscular contracture during the time preceding the surgical treatment. Experience had shown that the period of regeneration might extend from 18 months to several years.

In conclusion, he said that in war surgery, as well as in civil surgery, immediate suture of the nerves should usually be completely successful. If surgical treatment had been delayed from one month to two years, good functional results might occur in 40 to 50 per cent. of the cases. Even after this time treatment should be tried; it might be successful, but there was less chance. Nevertheless, it was his opinion that the surgical treatment of the big nerve trunks is by no means illusory if it were carefully practised by skilled specialists, and if the patient could be kept under prolonged observation.

Dr. Charles H. Frazier (Philadelphia) discussed the results of 3000 gunshot wounds of the peripheral nerves treated in the Reconstruction Hospitals under the control of the Surgeon-General's Office, U.S.A. Of these, about 2400 involved important nerves and 1800 were submitted to operations of various kinds, suture, lysis, or nerve transplants. Experience having shown that spontaneous recovery might take place up till six months after the injury, it was usual to delay operative procedure until the end of that period: further experience showed that successful suture could be performed after a lapse of two years. In three-quarters of the operations the procedure adopted was resection of the ends and suture; the technique was similar to that employed in other countries, and the actual resection tended to become more extensive with greater experience of the operator. Partial resection with suture was a delicate operation not often performed. When the resection had been so extensive that the ends could not be got together by any manoeuvre, such as transposition, he favoured a two-stage operation rather than "bridging" with a graft, since the results of the latter had, with only a few exceptions, been uniformly unsuccessful. As regards the quality of recovery from resection and suture, it was rarely perfect, and the question of the bearing of the intraneural plexuses on this elicited divergent views in America. It was difficult to account for the high percentage of failures in certain nerves—e.g., external popliteal. Neurolysis failed in 26 per cent. of cases. Finally, he considered that the results in these nerves were sufficiently good to warrant the re-exploration and suture if possible in cases of complete lesions of the median, ulnar, musculo-spiral, and sciatic. A complete statistical survey of the end-results was unfortunately prevented by the transference of the control of the cases to many different departments.

The Late Results of Surgical Intervention for Traumatic Lesions of Nerves.

Dr. A. Chiasserini read a paper by Dr. G. Verga (Pavia) who died recently. The part played by Italy in the study of the surgery of the peripheral nerves had been very important from a scientific point of view, thanks to the fundamental researches on the regeneration of nerves carried out at the Laboratory of Histology and General Pathology at the Royal University of Pavia, under the direction of Prof. Golgi. Dr. Verga himself had published the clinical results of 212 interventions on nerves (1916–18). It was only in a small minority of cases that we could obtain perfect recovery after surgical treatment. In a great many cases, considered to be successful, there was something lacking as regards sensibility or electric reactivity, or, perhaps, motility; in the latter case the operated limb was weaker and more easily tired. Usually the process of restoration of function stopped when only a more or less relative improvement was obtained. The precise estimation of the functional restoration of an operated nerve was always a delicate and difficult problem, and should only be undertaken by an experienced neurologist, who could have the cases under observation for a long time after operation. The percentage of improvement and recoveries obtained by Dr. Verga in 82 cases observed for over a year was (i.) recoveries, 52·4 per cent.; (ii.) improvements, 37·8 per cent.; (iii.) negative results, 9·7 per cent. He had included amongst the recoveries cases where a slight loss of strength or of function of the limb had been observed, and amongst the improvements all cases where, after operation, any favourable modification of the symptoms was manifest. Out of nine cases observed up to six and a half years after operation, only in one was a change for the worse observed. In all cases improvement had been the rule; this showed, he thought, that improvement is a question of time. The results obtained by suture and neurolysis were much superior to all other operations for making good great losses of nervous tissue. These other operations, however, should not be entirely condemned, because some of them, especially grafting, might give good results, but recourse should only be made to them where other means failed.

True End-results of Nerve Suture.

Mr. H. Platt (Manchester), who read a summary of a paper by himself and W. R. Bristow, said that the results of nerve suture had fallen short of expectations, as was shown by an analysis of the true end-results in 157 cases now published for the first time by Prof. J. B. Stopford. (See table on p. 174.)

The mere punctual appearance of the first signs of recovery was no indication that complete restoration of conductivity would eventually occur, and even in the very best results there was some departure from the normal. The most successful cases were those obtained in the musculo-spiral nerve, but even here the synergic action of the extensors of the wrist when "making a fist" rarely recovered. The median and ulnar nerves had both given disappointing results, the important sensory function of the former never having been completely restored. In the sciatic nerve the results again were poor; no case of recovery of the intrinsic muscles of the foot was recorded, and the type of sensory recovery had been defective, often leading to painful traumatic ulceration of the foot, for which amputation was sometimes demanded. *Neurolysis* (freeing or liberation of the nerve) when practised early, before the compression had resulted in degeneration of the axis cylinders, had given rapidly successful results in the return of both sensory and motor functions. But where the compression had been in existence for a long time the restoration of function depended upon regeneration of the axis cylinders through the interior of a nerve trunk, the seat of an interstitial fibrosis, and was therefore generally very incomplete. Nevertheless neurolysis was often a legitimate experiment to be followed by resection and suture at a later date, if signs of recovery did not ensue. *When nerve-suture failed*, an alternative procedure available in certain cases was tendon transplantation; this had been employed chiefly for musculo-spiral lesions, the pronator radii teres, flexor carpi radialis, and flexor carpi ulnaris being transplanted into the extensors

Arthroplasty had, in fact, created a new chapter in surgery.

Dr. Leriche gave it as his own experience of 25 cases of ankylosis of the elbow, 15 of which had been treated by Ollier's method and the remainder by arthroplasty with interposition, that the results of the former were at least as good as those of the latter. After seeing Dr. Putti's results, however, there could no longer be any doubt that arthroplasty of the knee was preferable to a stiff joint in the best position (full extension), which was at times very inconvenient to the patient.

DISCUSSION.

Sir William Macewen (Glasgow) pointed out that flail joints did not result from the old-fashioned excision provided the resection were kept within the limits of the capsule. The function of the interposed flap he believed was to limit the growth of bone from the raw bony surfaces; it was more important when the diaphysis was involved on account of the greater osteogenetic power of the diaphysis as compared with the epiphysis. He thought that movement might have been improved in some of the cases by a larger resection of bone. Dr. Putti's arthroplasty of the knee was undoubtedly a great advance in surgery.

Mr. R. C. Elmslie (London) considered that a knowledge of when to perform arthroplasty was more important than skill in the technique of the operation. One stiff joint might be very little disability; he knew of cases with an ankylosed hip who could walk ten miles, whereas a mobilised joint might be a great disability if, as sometimes happened, it were painful. Double ankylosis of the hip might call for a mobilising operation on one side, but as a rule arthroplasty was more often indicated in the upper than in the lower extremity. In respect of the shoulder arthroplasty failed to reproduce the complicated movements of the joint. In the elbow he obtained very satisfactory functional results by an excision, shaping the olecranon and preserving the triceps, without any flap interposition.

Sir W. I. de Courcy Wheeler (Dublin) said that arthroplasty of the shoulder was only indicated when scapular movement was deficient; bony ankylosis was better for a working man. It was unfortunate that no satisfactory results had yet been obtained from arthroplasty of the finger-joints; following Murphy, he had tried the interposition of discs of cartilage, but without success. He had performed successfully a double arthroplasty of the knee, but was cautious in advising the operation. Since early painless movement was necessary if a new joint were to be formed, he urged the necessity for excision of all remains of capsule and ligaments which carried nerves. In the hip he had been disappointed with his own results, although he had seen many encouraging results of others. Finally, he described the operation of cheilotomy (the resection of osteophytic masses) as having given astonishingly good result in osteoarthritis of the hip.

Dr. Jiraseck (Prague) gave the results of 25 arthroplasties at Prof. Kukula's clinic. The interposed flap consisted of omental fat in 9 cases, of subcutaneous fat in 7 cases, and of fascia lata in 9 cases. The most successful cases were in the elbow (88 per cent. successful) and knee (77 per cent. successful), while the one case of arthroplasty of the hip failed. Re-ankylosis, when it occurred, was due to the return of suppuration, or to lack of cöoperation on the part of the patient.

Dr. Villandre (Barcelona) described his results in arthroplasty of the jaw and elbow, and illustrated them by lantern slides.

Mr. R. A. Stoney (Dublin) considered arthroplasty unnecessary where excision gave a good movable joint. In the elbow in cases of war wounds he had obtained good results from excision (limited as regards the bones of the forearm, but more radical as regards the humerus), being careful to preserve the attachment of the triceps to the periosteum. The cavity left was packed with "bipped" gauze and later allowed to close by granulation.

Dr. T. Tuffier (Paris) found that the greatest difficulty in performing Putti's operation on the knee was to obtain and preserve the right gap between the new articular surfaces. To obviate this he employed a pair of jointed steel plates attached to the femur and tibia by screws; this was allowed to remain in place for about a month, during which it allowed of movements and abolished the need for extension. It was then removed under local anæsthesia.

Drs. Corachan (Barcelona), Zahradnicky (Prague), Ribas y Ribas (Barcelona), Puiz y Sureda (Barcelona), and Juracz (Posen) also spoke.

On Wednesday evening the members of the Congress were entertained at a reception by the Lord Mayor and Lady Mayoress at the Mansion House.

On Wednesday afternoon, at an "unofficial" meeting, Dr. Serge Voronoff (Paris) gave a further demonstration on the subject of testicular grafting, illustrated by cinematograph pictures of his experimental work on rams and goats, and of the results obtained in man. Dr. Pauchet (Paris) described the technique of blood transfusion, and also illustrated the methods employed by cinematograph pictures.

THURSDAY, JULY 19TH.

Nerve Injuries.

Dr. P. Henriksen (Skien) discussed the results of surgical treatment of injury of the nerves. He said that after a nerve had been cut with a sharp instrument the peripheral nerve tended to heal spontaneously without leaving any permanent injury. Sensibility reappeared as soon as there was contact between the nerve ends, and mobility after about two months. After a nerve had been sutured, function developed in the same way as in spontaneous healing if the suture had been correctly performed. But healing might not take place if fat were interposed, or if infection resulted. After secondary suture, sensibility appeared at once and mobility and the reactions to electrical currents might occur after two months, and develop as after primary suture. If the nerve were subjected to blunt force, such as crushing or tearing, the neurilemma nuclei were injured and some completely destroyed, so that part of the newly formed nerve fibres were not capable of living and degenerated. When the neurilemma nuclei were totally destroyed no new nerve fibres were formed and the nerve atrophied. The changes were most marked at the actual spot where the crushing took place, and the nerve was adherent to surrounding tissue. Improvement might be obtained in some instances by freeing the nerve from adhesions. The best method seemed to be to resect the thickened fibrous part. The degree of function secured then depended on the general state of the nerve.

Prof. A. Gosset (Paris) thought that the following cases of nerve wounds should be operated on:—

(*a*) *Cases of Progressive Compression Causing Serious Irritation or Interruption.*—In these types liberation could not injure the patient or the nerve, and he saw no advantage in delaying the operation.

(*b*) *All Cases of Complete Interruption.*—These should be clinically examined by competent neurologists, and if they showed no sign or regeneration, or showed signs of useless regeneration, should be operated on.

(*c*) *All Cases of Causalgias or Serious Neuritis.*—There was, however, no fixed rule for this latter type.

He said that war surgery had shown us that we should certainly, during the preliminary surgical cleaning of the wound, examine the state of the important vessels and nerves. This was still more necessary if from the first day there were signs of paralysis of a large peripheral nerve trunk. Any severed nerve should at once be stitched up to allow of rapid regeneration, and, moreover, to avoid formation of fibrous tissue. When the nerve was bruised, it seemed best to preserve it and keep it under constant observation. When some time had elapsed before the patient had received medical attention, the lesion should be operated on as quickly as possible. Aseptic operation, however, was essential, and it might be necessary to wait some weeks until all signs of suppuration had disappeared. As regards the operation to be done, Prof. Gosset thought that in the case of nerve compression with signs of irritation, simple liberation was all that was necessary. Intra-nervous extraneous bodies should always be taken out, but small intrafascicular fibromata should be enucleated only when the operation was without danger to the healthy nerve bundles. If there were interruption in the continuity of the nerve which showed no improvement after several examinations, resection of the fibrous callus and suture of the neurilemma should be undertaken. If suture were impossible, a graft, or the dividing into two of the lower end, should be practised. Good results would only be obtained if the patient had been kept free from ankylosis and muscular contracture during the time preceding the surgical treatment. Experience had shown that the period of regeneration might extend from 18 months to several years.

In conclusion, he said that in war surgery, as well as in civil surgery, immediate suture of the nerves should usually be completely successful. If surgical treatment had been delayed from one month to two years, good functional results might occur in 40 to 50 per cent. of the cases. Even after this time treatment should be tried; it might be successful, but there was less chance. Nevertheless, it was his opinion that the surgical treatment of the big nerve trunks is by no means illusory if it were carefully practised by skilled specialists, and if the patient could be kept under prolonged observation.

Dr. Charles H. Frazier (Philadelphia) discussed the results of 3000 gunshot wounds of the peripheral nerves treated in the Reconstruction Hospitals under the control of the Surgeon-General's Office, U.S.A. Of these, about 2400 involved important nerves and 1800 were submitted to operations of various kinds, suture, lysis, or nerve transplants. Experience having shown that spontaneous recovery might take place up till six months after the injury, it was usual to delay operative procedure until the end of that period; further experience showed that successful suture could be performed after a lapse of two years. In three-quarters of the operations the procedure adopted was resection of the ends and suture; the technique was similar to that employed in other countries, and the actual resection tended to become more extensive with greater experience of the operator. Partial resection with suture was a delicate operation not often performed. When the resection had been so extensive that the ends could not be got together by any manœuvre, such as transposition, he favoured a two-stage operation rather than "bridging" with a graft, since the results of the latter had, with only a few exceptions, been uniformly unsuccessful. As regards the quality of recovery from resection and suture, it was rarely perfect, and the question of the bearing of the intraneural plexuses on this elicited divergent views in America. It was difficult to account for the high percentage of failures in certain nerves—e.g., external popliteal. Neurolysis failed in 26 per cent. of cases. Finally, he considered that the results in these nerves were sufficiently good to warrant the re-exploration and suture if possible in cases of complete lesions of the median, ulnar, musculo-spiral, and sciatic. A complete statistical survey of the end-results was unfortunately prevented by the transference of the control of the cases to many different departments.

The Late Results of Surgical Intervention for Traumatic Lesions of Nerves.

Dr. A. Chiasserini read a paper by Dr. G. Verga (Pavia) who died recently. The part played by Italy in the study of the surgery of the peripheral nerves had been very important from a scientific point of view, thanks to the fundamental researches on the regeneration of nerves carried out at the Laboratory of Histology and General Pathology at the Royal University of Pavia, under the direction of Prof. Golgi. Dr. Verga himself had published the clinical results of 212 interventions on nerves (1916–18). It was only in a small minority of cases that we could obtain perfect recovery after surgical treatment. In a great many cases, considered to be successful, there was something lacking as regards sensibility or electric reactivity, or, perhaps, motility; in the latter case the operated limb was weaker and more easily tired. Usually the process of restoration of function stopped when only a more or less relative improvement was obtained. The precise *estimation of the functional* restoration of an operated nerve was always a delicate and difficult problem, and should only be undertaken by an experienced neurologist, who could have the cases under observation for a long time after operation. The percentage *of improvement and recoveries* obtained by Dr. Verga in 82 cases observed for over a year was (i.) recoveries, 52·4 per cent.; (ii.) improvements, 37·8 per cent.; (iii.) negative results, 9·7 per cent. He had included amongst the recoveries cases where a slight loss of strength or of function of the limb had been observed, and amongst the improvements all cases where, after operation, any favourable modification of the symptoms was manifest. Out of nine cases observed up to six and a half years after operation, only in one was a change for the worse observed. In all cases improvement had been the rule; *this showed*, he thought, that *improvement is a question of time*. The results obtained by suture and neurolysis were much superior to all other operations for making good great losses of nervous tissue. These *other operations*, however, should not be entirely condemned, because some of them, especially grafting, might give good results, but recourse should only be made to them where other means failed.

True End-results of Nerve Suture.

Mr. H. Platt (Manchester), who read a summary of a paper by himself and W. R. Bristow, said that the results of nerve suture had fallen short of expectations, as was shown by an analysis of the true end-results in 157 cases now published for the first time by Prof. J. B. Stopford. (See table on p. 174.)

The mere punctual appearance of the first signs of recovery was no indication that complete restoration of conductivity would eventually occur, and even in the very best results there was some departure from the normal. The most successful cases were those obtained in the musculo-spiral nerve, but even here the synergic action of the extensors of the wrist when "making a fist" rarely recovered. The median and ulnar nerves had both given disappointing results, the important sensory function of the former never having been completely restored. In the sciatic nerve the results again were poor; no case of recovery of the intrinsic muscles of the foot was recorded, and the type of sensory recovery had been defective, often leading to painful traumatic ulceration of the foot, for which amputation was sometimes demanded. *Neurolysis* (freeing or liberation of the nerve) when practised *early*, before the compression had resulted in degeneration of the axis cylinders, had given rapidly successful results in the return of both sensory and motor functions. But where the compression had been in existence for a long time the restoration of function depended upon regeneration of the axis cylinders through the interior of a nerve trunk, the seat of an interstitial fibrosis, and was therefore generally very incomplete. Nevertheless neurolysis was often a legitimate experiment to be followed by resection and suture at a later date, if signs of recovery did not ensue. *When nerve-suture failed*, an alternative procedure available in certain cases was tendon transplantation; this had been employed chiefly for musculo-spiral lesions, the pronator radii teres, flexor carpi radialis, and flexor carpi ulnaris being transplanted into the extensors

Nerve-grafting.

Mr. W. R. Bristow (London) continued the joint report. "Nerve-grafting" (i.e., the bridging of a gap in a nerve after resection or from injury with a portion of nerve obtained from the same or another individual) must be regarded as a last resort; every effort should first be made and every device employed to obtain end-to-end suture. Many claims to success from grafting had been examined by the Medical Research Council and all had failed to convince. Most of the claims were based on the presence of "trick-movements"; thus with a complete median lesion the patient often learnt to flex the wrist by means of the extensor ossis metacarpi pollicis. Microphotographs showing the results of nerve-suture were then shown. It was pointed out that interstitial fibrosis due to an ascending toxic neuritis was demonstrable in one section two and a half inches proximal to the end bulb; in such a case it would be impossible to excise all the damaged nerve before suture, and this explained the frequency of partial or total failure in suture of war injuries. A section of a "nerve-graft" removed three and a half years after implantation was also displayed which illustrated the reaction around a stitch and showed the total failure of axons from the central end to grow into the substance of the graft. Another section of nerve obtained from a limb amputated for pain showed demyelination. Drawings of microscopic sections of muscle (1) after two and a half years denervation; (2) in ischæmic paralysis showed that in the former, in which recovery was still possible, the transverse striation of the muscle fibres was lost and fibrous tissue increased, while in the latter the sarcolemma nuclei had disappeared and the muscle fibres were beyond recovery. Finally, he pointed out that the joint report was based upon the results of war injuries, and that the results of suture of nerve injuries in civil practice, where sepsis should not play so large a part, should be much better.

DISCUSSION.

Dr. R. Leriche (Lyons) discussed causalgia, which he had found was not infrequently associated with a gross arterial or nervous lesion, although sometimes no such lesion was to be found. That causalgia was not psychic in origin was proved by the fact that cases which originated in 1914 or 1915 were still suffering in spite of the end of the war, and by the occasional occurrence of causalgia in civil injuries. While causalgia was the result of a peripheral lesion operation was successful, but as soon as the lesion had spread to the nerve roots or the cord operation was less successful. Believing that pain was carried by the sympathetic nerves, he had performed exsection of the sympathetic in nine cases, with five good results, two improvements, and two failures. Primary exsection of a portion of the involved nerve trunk had been performed three times, with one cure and two failures. In the cured case subsequent suture was performed, but the result was not seen as the patient died of another malady; 17 late exsections gave only one success. Sympathetic exsection was only useful for cases of functional disturbance, unassociated with demonstrable anatomical change.

Mr. Archibald Young (Glasgow) held a brief for the value of a sheath (either of vein, fat, or muscle) around a sutured nerve; 33 cases in which he had employed such a sheath, when contrasted with others in which no sheath was employed, showed a higher standard of recovery. The bed of a sutured nerve was also important; he considered displacement from its original bed to be an important part of the technique of nerve-suture. He had had some success with nerve-bridging.

Dr. A. Chiasserini (Rome) agreed that end-to-end suture gave the best results, but claimed to have had a success from the implantation of a graft preserved in alcohol in a case where the median nerve was severed in the forearm. The sensory recovery was good, and the motor recovery moderate. He then gave details, illustrated by lantern slides, of experimental work on nerve-grafting in dogs. The best results were obtained with autogenous grafts, but good results accrued from homogeneous. When removed some months later the nerve appeared almost normal, and histologically nerve fibres could be traced through the graft, especially in its periphery, to the distal end. Such nerves responded to faradisation. Wrapping the suture line at the primary operation was wrong, but might be useful as a secondary measure when adhesions were preventing the growth of the nerve fibres along the periphery. He concluded that the almost universal failure of nerve-grafts in man was due to faulty technique.

In the afternoon the Royal College of Physicians was opened to members of the Congress, and there was an exhibition of specimens of surgical and anatomical interest.

On Thursday evening a reception was held at the Royal College of Surgeons, Lincoln's Inn Fields.

Members of the Congress were received by the President, Sir John Bland-Sutton, and Lady Bland-Sutton, and by Mr. and Mrs. H. J. Waring. A number of Hunterian relics were exhibited.

FRIDAY, JULY 20TH.

Serotherapy and Vaccinotherapy in Surgery.

Dr. Louis Bazy's (Paris) paper was read by Dr. Michel, who said that doubtless the knowledge of the paraspecific effects of serums and vaccine (Widal's colloidoclasic shock, effect of Nolf's peptone) had its use, but in the present state of our knowledge we could not make full uses of the resources of serotherapy and vaccinotherapy if we did not recognise the idea of specificity. Apart from such, especially antitoxic sera (such as antitetanic serum, antigangrene serum, the efficacy of which had been amply proved), most of those used in surgery were less certain in their effect. He therefore thought it advisable to direct attention to local applications of serotherapy. This might prove of the greatest use to surgeons. It was also necessary to insist on the fact that repeated injections of serum became less and less effective, and therefore they should only be used in cases of extreme need, and then only as a last resort. The object of the use of vaccines was to produce artificially in the organism a state similar to the one in which it would be if it had recovered from an ordinary attack of the disease in question (Bordet). This definition showed that in surgery vaccination was of no practical value, as surgical infections when healed do not confer immunity. Recourse is mostly made to vaccinotherapy. This consisted in treating the disease during its development by injection of the specific germ more or less modified. Again, use might be made of bacteriotherapy. Here microbic products were used which had no connexion with the disease that was being treated. Another method was to try a "mixed immunisation," employing sera and vaccines—this might be called serovaccination. Generally speaking, sera should be used to produce a quick, but not a lasting, effect in cases of urgency. But vaccines gave only slow results, which were, however, more lasting. Serotherapy and vaccinotherapy were most valuable to the surgeons; they facilitated surgical treatment and localised it, but neither sera nor vaccines were of any use in necrosis or cicatricial lesions. Attention should be paid to signs of susceptibility to microbes on the part of "germ bearers," for most cases of "operative shock" are due to the sudden development of a germ, whose virulence had increased under conditions which had become less able to combat it. The skilful use of serotherapy and vaccines would enable us to anticipate and to counteract this susceptibility.

DISCUSSION.

Mr. D. P. D. Wilkie (Edinburgh), recognising that the mortality from operations on the large intestine arose chiefly from sepsis, either as wound suppuration, peritonitis, or thrombosis of large veins (the causal organism being the streptococcus or the *Bacillus coli*), had performed some animal experiments with a view to discovering whether it would not be possible to acquire some degree of immunity to those organisms. Both vaccines and the injection of nucleic acid were found to increase the resisting powers of animals, and a combination of both so raised the resistance that the animal could withstand the injection of 3 M.L.D. of the organism into the peritoneum. He had therefore introduced this practice into his routine preparation for such operations as colectomy or the closure of a fæcal fistula. Ten days before operation a dose of 10,000,000 streptococcal vaccine was given, and this was repeated three days before operation: on the night before operation a dose of 2 per cent. nucleic acid was given which resulted in a leucocytosis of 12,000. Sixty-three operations had been performed after this type of preparation with two deaths, neither of them from sepsis.

Dr. de Zawadski (Warsaw) had found vaccinotherapy very useful in cases of serious cervical suppuration, peritonitis, and empyema. It would not save all cases, but was a great help to rapid recovery.

Sir Almroth Wright (London) suggested increasing the resistance of the body before certain operations, such as extraction of teeth and tonsillectomy, and the removal of cancers; the latter were often infected by the staphylococcus and the streptococcus before coming to the surface. The failure of antiseptics in war surgery could have been foretold from laboratory experiments, since antiseptics when mixed with blood formed a better culture medium than blood alone. As regards vaccinotherapy, it was now apparent that not all bacterial infections could be successfully treated by vaccines (Pasteur's original view), for the combating of infection was carried on by two separate mechanisms: (1) by antibacterial substances in the blood, and (2) by phagocytosis by the leucocytes. In certain very acute infections the leucocytes were poisoned and unable to carry on phagocytosis, even in the presence of large quantities of antibacterial substances in the blood. The fact that so many different varieties of vaccines (complete and partial antigens, sensitised, detoxicated and defatted vaccines) had been employed showed that there was something wrong in the application of vaccine therapy. What was wrong was the dosage, which ought to be controlled by the response made by the body fluids. This was easily tested "in vitro," and if it was found that the addition of vaccine to the patient's blood resulted in a decrease of phagocytosis, it was certain that the administration of the vaccine would be harmful. In such cases, and in severe infections where no phagocytosis was occurring although the opsonic power of the serum was raised above normal, what was required was a number of healthy leucocytes. This call could be met by immuno-transfusion—i.e., the transfusion of 500 c.cm. of defibrinated blood from a donor previously immunised by a vaccine. It was important that the blood should be defibrinated and not citrated, as citrates adversely affected the leucocytes. He considered that passive immunisation with horse or other alien serum was useless.

Dr. Leclercq (Morristown, New Jersey), Dr. Zahradnicky (Prague), and Dr. Mayer (Brussels) also spoke.

Operative Shock.

Dr. George W. Crile (Cleveland, U.S.A.) read a paper on an Electrochemical Interpretation of Shock and Exhaustion. He elaborated a theory that man and animals are electrochemical mechanisms constructed on the pattern of the constituent cells, each of which in itself was an electrochemical mechanism. The difference in potential in the cells was maintained by oxidation. The brain had the highest rate of oxidation and the liver the lowest, hence he suggested the hypothesis that the positive pole was the brain and the negative the liver; the connecting wires were the nerves, and the salts in solution the electrolytic fluid in which the electrochemical mechanism was immersed. This hypothesis would interpret the fact that when the liver or the brain was removed the organism perished; if the animal were deprived of oxygen, the difference of potential within the cells would be lost and death would result. It would explain the essential rôle of water in living processes—i.e., as a non-conductor and a solvent attaining ionisation. Chemical action and electric conductivity were controlled by heat and cold; abdominal surgery in the colder months in unwarmed front area huts illustrated the fact that there was probably a lethal cold and a lethal warm temperature for this electrochemical mechanism. The electrochemical theory would interpret the specific antithetic action of adrenalin upon the temperature of the brain and of the liver and other organs in the splanchnic area. It would interpret the increase in electric conductivity of the brain by iodine, iodoform, and thyroid extract (hyperthyroidism); and the decreased conductivity of the brain after thyroidectomy. It would interpret the interference with digestion by the strong emotions, by injury, by pain, by infections, &c., for the splanchnic

Finally, he pointed out that the joint report was based upon the results of war injuries, and that the results of suture of nerve injuries in civil practice, where sepsis should not play so large a part, should be much better.

DISCUSSION.

Dr. R. Leriche (Lyons) discussed causalgia, which he had found was not infrequently associated with a gross arterial or nervous lesion, although sometimes no such lesion was to be found. That causalgia was not psychic in origin was proved by the fact that cases which originated in 1914 or 1915 were still suffering in spite of the end of the war, and by the occasional occurrence of causalgia in civil injuries. While causalgia was the result of a peripheral lesion operation was successful, but as soon as the lesion had spread to the nerve roots or the cord operation was less successful. Believing that pain was carried by the sympathetic nerves, he had performed exsection of the sympathetic in nine cases, with five good results, two improvements, and two failures. Primary exsection of a portion of the involved nerve trunk had been performed three times, with one cure and two failures. In the cured case subsequent suture was performed, but the result was not seen as the patient died of another malady; 17 late exsections gave only one success. Sympathetic exsection was only useful for cases of functional disturbance, unassociated with demonstrable anatomical change.

Mr. Archibald Young (Glasgow) held a brief for the value of a sheath (either of vein, fat, or muscle) around a sutured nerve; 33 cases in which he had employed such a sheath, when contrasted with others in which no sheath was employed, showed a higher standard of recovery. The bed of a sutured nerve was also important; he considered displacement from its original bed to be an important part of the technique of nerve-suture. He had had some success with nerve-bridging.

Dr. A. Chiasserini (Rome) agreed that end-to-end suture gave the best results, but claimed to have had a success from the implantation of a graft preserved in alcohol in a case where the median nerve was severed in the forearm. The sensory recovery was good, and the motor recovery moderate. He then gave details, illustrated by lantern slides, of experimental work on nerve-grafting in dogs. The best results were obtained with autogenous grafts, but good results accrued from homogeneous. When removed some months later the nerve appeared almost normal, and histologically nerve fibres could be traced through the graft, especially in its periphery, to the distal end. Such nerves responded to faradisation. Wrapping the suture line at the primary operation was wrong, but might be useful as a secondary measure when adhesions were preventing the growth of the nerve fibres along the periphery. He concluded that the almost universal failure of nerve-grafts in man was due to faulty technique.

In the afternoon the Royal College of Physicians was opened to members of the Congress, and there was an exhibition of specimens of surgical and anatomical interest.

On Thursday evening a reception was held at the Royal College of Surgeons, Lincoln's Inn Fields.

THE LANCET.

LONDON: SATURDAY, JULY 28, 1923.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE annual meeting of the British Medical Association, which is drawing to a close at Portsmouth, was held in an expansive mood. Its membership has reached the high-water mark of 1912 and there is no reason to anticipate the ebb which then followed, for dissension within the ranks over the broad principles of insurance practice is practically at an end, and the panel executive is looking forward with confidence to an amicable settlement of the outstanding question of the cash value of medical benefit to the community. The chairman of the body which has been conducting the matter received from the meeting a gratifying endorsement of past policy and a free hand for the immediate future. The financial situation of the Association is indicated by the fact that the treasurer did not blench at the proposal to disburse £100,000 or so in the purchase and adaptation of a new home which has been acquired in the neighbourhood of Tavistock-square, or even at the additional outlay of £50,000 which would provide for the social amenities long desired by members of the Association resident outside the metropolitan area. The building as it stands possesses artistic merit, affords sufficient scope for present activities, and contains a hall large enough for meetings of representatives. Situated within a stone's-throw of what is presumably the new site of London University, the officers of the Association foresee the possibility of making the house a nucleus of organised post-graduate teaching in London. A substantial sum is already set apart by the treasurer for the granting of research scholarships, and the chairman of the Science Committee desires to increase this sum. A third source of quiet satisfaction lay in the continuing success of the Journal of the Association, under the editorship of Sir DAWSON WILLIAMS, to whom warm congratulation was tendered on the completion of 25 years in the editorial chair.

The new President of the Association, Mr. C. P. CHILDE, chose for his inaugural address on Tuesday the subject of "Environment and Health." An abstract of his address appears at the front of our present issue. Speaking as the chairman of the Portsmouth Health and Housing Committee, Mr. CHILDE dwelt on the need for concentration on the prevention of disease, and on strengthening resistance to disease by the improvement of environment, rather than on the search for cures or palliatives when the damage is already done; and on care for the environment of the wage-earning classes as the greatest of all the problems of preventive medicine. Coming from one who is also senior surgeon to the Royal Portsmouth Hospital, these remarks will have carried the greater weight; they illustrate well the "whole-hearted joining of hands for a common purpose" described in his address as the best evidence of a loyal and healthy citizenship. We shall hardly be wrong in thinking that Mr. CHILDE had also in mind with no little satisfaction the signs of reconciliation between preventive and remedial methods within the borders of the Association. The rift ever growing wider between the aims of the Society of Medical Officers of Health and the British Medical Association has now been bridged by the mutual acceptance of a scheme for coöperation which permits of a common declaration of policy on general lines and which precludes the Society from taking independent medico-political action. This decision, ratified by the Representative Meeting at its first session, is the result of negotiations which have been in train since the annual gathering at Cambridge three years ago, and goes far deeper than the mere agreement on rates of salary and tenure of office, important as these are. The conference which drew up the scheme recognised that "benefit would be likely to result from a closer coöperation of the local medical profession with the local authorities' schemes of medical survey or inspection and treatment," and one of the first fruits of this recognition is the working agreement, which we chronicled last week, between practitioners and civic council in the urban district of Willesden, where the two policies had been allowed to grow apart until reconciliation became difficult and tedious. In Portsmouth there has been no such divergence, although the sanitary authority is keen. In many other places similar divergence must have arisen if the advocates of both policies had been as keen as they were at Willesden. Within the British Medical Association itself there will now be the reconciling influence. A great opportunity has not been lost.

◆

CANCER FACTS AND CANCER THEORIES.

FOR hundreds of years cancer has occupied the attention of physicians and surgeons, and it would be impossible to estimate the expenditure of time and energy on this absorbing subject since the doctrine of cellular pathology was first developed. It would be too much to hope that this labour has always been wisely directed or accurately performed. Much of it has resulted in knowledge which is permanent, but much more has clogged the literature with doubtful if not inaccurate statements, so that year by year the subject becomes more obscure, and the modern investigator finds his task not always lightened by the work of his predecessors, and rendered sometimes more difficult. Numberless examples of this could be quoted, but two will suffice. What are the actual results of operation in, say, cancer of the breast? What is the proportion of absolute cures, and how do the modern operations compare with the old, either as palliative or curative measures? Accurate answers to these questions are difficult to obtain, and, furthermore, there is a tendency for the written word to be forgotten though the personal impression processes were inhibited while the brain was stimulated. It would interpret the antithetic effects of fear and faith, and the failure of the health in man and animals under the stress of chronic fear or anger or other strong emotions. This theory would interpret the essential function of sleep as the period during which the difference in potential in the batteries which drive the organism, which had been decreased by the activities of the day, was restored. It would interpret the fact that in surgical operations, if a state of negativity and the internal respiration were maintained, there would be no surgical shock. The state of negativity was maintained by: (*a*) Exclusion of fear by management, by operation in the patient's room, by morphine, by analgesia; (*b*) exclusion of traumatic stimuli by local or regional anæsthesia, by gentle handling, by protection of the wounds from the irritation of air; (*c*) exclusion of stimulation by stimulant drugs. The entire process whereby the state of negativity was secured and the internal respiration—difference in potential—was maintained was included in the combination of methods of pre- and post-operative management and of surgical technique which was called *anociation*. The internal respiration was maintained by fluids, by warmth, by blood transfusion, by rest, by sleep, and by the avoidance of deep inhalation anæsthesia. Finally, and included in the above, the theory that man is an electrochemical mechanism interpreted many of the phenomena of life.

Traumatic Shock from a Clinical Point of View.

Dr. P. Mocquot read a paper which was the combined work of himself and his colleagues, Drs. M. Quénu and P. Duval. They showed the evolution of ideas concerning shock, and pointed out what the Medical Research Council and the Société Nationale de Chirurgie de France had done. They then turned to the clinical side of the subject, and laid stress on the early appearance of the peculiar symptoms of traumatic shock, and gave a list, based mostly on cases during the war, of the various signs, such as low temperature, low blood pressure, blood and urine analysis, &c. In addition to the recognised type they described a type of mitigated shock, often met with in ordinary surgery, caused by attrition of the tissues. It outlined a new chapter of surgical pathology. The prognosis of traumatic shock might be estimated by the temperature, blood pressure, and by the analysis of the blood and urine. The recovery of kidney function, the excretion of urea, and the diminution of the urea-content of the blood were the most favourable signs. Therapeutic treatment included prophylactic measures and the treatment of the shock when it occurred. Prompt medical and surgical treatment were a sine qua non of prophylactic care. The best surgical treatment consisted in the excision of the wound; immunisation by means of an anti-shock serum had not yet proved its efficiency, at least from a clinical point of view. The treatment of an ascertained case of shock might be symptomatic. The former was especially useful as a means of first aid. Causal treatment was grounded on the new view of shock as an intoxication, the seat of which was the traumatic lesion. Theoretically, the wound which gave rise to the toxins should be excised. Practically we were confronted with two separate questions as to whether the affected limb should or should not be amputated. In the former case recourse should be had to "primary" amputation. In the latter case the treatment should consist of thorough excision of the wound, and the devitalised parts should be cut out as widely as possible. The operation should be quick. The wound was sprinkled with hypertonic solution and no attempt should be made at first to bring the edges of the wound together. Further research was yet required to decide on the most suitable anæsthetic.

Mr. John Fraser (Edinburgh) pointed out that surgical shock arose from various causes, such as injury to a sensitive part like the hand, from the early symptoms of peritonitis, burns in a child, and extensive crushing injuries of the limbs. Whatever its origin, the essential feature of shock remained constant—namely, diminution of the volume of blood from its passage into the vast capillary system where it was not under the control of the bulbar vasomotor centre. The extent of this capillary system would be realised from the fact that if placed in line the capillaries of the human body would extend two and a half times around the world. There was growing evidence that these capillaries had an independent muscle system, and recently in observations on the swim-bladder of the eel he had seen dilatation of the capillaries occur from the shock of cutting.

Dr. Pauchet (Paris) held that all the symptoms of shock disappeared rapidly after oxygenated blood transfusion by Bécart's method. Operation shock should be avoided by a preliminary blood transfusion, repeated if necessary during the progress of the operation; transfusion should not be left until it was obviously useless. The effects of oxygenated blood transfusion were a lasting rise of blood pressure and improvement in the patient's condition from the supply of oxygen to the central nervous and endocrine systems: further acidosis was neutralised.

Dr. Ufreduzzi (Turin) said that in states of traumatic shock he used local or splanchnic anæsthesia for operations. He found it difficult to believe that the substance or toxin which produced shock came from injured muscle, since operation confined to muscle was not attended with shock.

Dr. Jiraseck (Prague) and Dr. de Zawadski also spoke.

Dr. W. W. Keen (Philadelphia) proposed a vote of thanks to the President and officers, naming especially Dr. Mayer, the secretary-general, and Sir D'Arcy Power and Mr. J. E. H. Roberts, the British organising secretaries, to whose work the success of the Congress was largely due. This was carried with acclamation, and Sir William Macewen replied.

It was announced that the next Congress of the Society would be held at Rome in 1926 under the presidency of Dr. Giordano (Venice), when the subjects for discussion would be (1) the Surgery of the Spleen, (2) Cerebral Tumours, (3) Radio-therapy in Uterine Cancer, and two other subjects to be chosen later by the scientific committee consisting of Mr. Percy Sargent (U.K.), Dr. Gosset (France), Dr. Alessandri (Italy), Dr. Henschen (Switzerland), and Dr. Ribas y Ribas (Spain).

The annual banquet was held on Friday, July 20th, at the Trocadero Restaurant, with Sir William Macewen, F.R.S., in the chair. The large company included the Presidents of the Royal Colleges of Physicians and Surgeons and of the leading London medical societies. Sir William Macewen toasted the foreign delegates, and Messrs. Alessandri, Mayer, Haussen, Petridis, Koch, Nicolaysen, de Lawadski, Kayser, de Quervain, and Crile, representing Italy, Belgium and France, Denmark, Egypt, Holland, Norway, Poland, Sweden, Switzerland, and the United States of America respectively, replied. The speeches dwelt almost entirely with the feelings of gratitude felt by the delegates for the hospitality which had been shown them in London, for the interesting work which they had inspected in the hospitals, and the excellent papers to which they had listened at the Conference. The next Conference in Rome was frequently mentioned and most hopeful anticipations were expressed that a large number of their London colleagues would be present to meet the foreign delegates.

INDEX TO "THE LANCET," VOL. I., 1923.

THE Index and Title-page to Vol. I., 1923, which was completed with the issue of June 30th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2.

ROYAL SOCIETY OF MEDICINE.—The William Gibson Research Scholarship has been awarded to Miss M. Forrester-Brown, of Dundee.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE annual meeting of the British Medical Association, which is drawing to a close at Portsmouth, was held in an expansive mood. Its membership has reached the high-water mark of 1912 and there is no reason to anticipate the ebb which then followed, for dissension within the ranks over the broad principles of insurance practice is practically at an end, and the panel executive is looking forward with confidence to an amicable settlement of the outstanding question of the cash value of medical benefit to the community. The chairman of the body which has been conducting the matter received from the meeting a gratifying endorsement of past policy and a free hand for the immediate future. The financial situation of the Association is indicated by the fact that the treasurer did not blench at the proposal to disburse £100,000 or so in the purchase and adaptation of a new home which has been acquired in the neighbourhood of Tavistock-square, or even at the additional outlay of £50,000 which would provide for the social amenities long desired by members of the Association resident outside the metropolitan area. The building as it stands possesses artistic merit, affords sufficient scope for present activities, and contains a hall large enough for meetings of representatives. Situated within a stone's-throw of what is presumably the new site of London University, the officers of the Association foresee the possibility of making the house a nucleus of organised post-graduate teaching in London. A substantial sum is already set apart by the treasurer for the granting of research scholarships, and the chairman of the Science Committee desires to increase this sum. A third source of quiet satisfaction lay in the continuing success of the Journal of the Association, under the editorship of Sir DAWSON WILLIAMS, to whom warm congratulation was tendered on the completion of 25 years in the editorial chair.

The new President of the Association, Mr. C. P. CHILDE, chose for his inaugural address on Tuesday the subject of "Environment and Health." An abstract of his address appears at the front of our present issue. Speaking as the chairman of the Portsmouth Health and Housing Committee, Mr. CHILDE dwelt on the need for concentration on the prevention of disease, and on strengthening resistance to disease by the improvement of environment, rather than on the search for cures or palliatives when the damage is already done; and on care for the environment of the wage-earning classes as the greatest of all the problems of preventive medicine. Coming from one who is also senior surgeon to the Royal Portsmouth Hospital, these remarks will have carried the greater weight; they illustrate well the "whole-hearted joining of hands for a common purpose" described in his address as the best evidence of a loyal and healthy citizenship. We shall hardly be wrong in thinking that Mr. CHILDE had also in mind with no little satisfaction the signs of reconciliation between preventive and remedial methods within the borders of the Association. The rift ever growing wider between the aims of the Society of Medical Officers of Health and the British Medical Association has now been bridged by the mutual acceptance of a scheme for coöperation which permits of a common declaration of policy on general lines and which precludes the Society from taking independent medico-political action. This decision, ratified by the Representative Meeting at its first session, is the result of negotiations which have been in train since the annual gathering at Cambridge three years ago, and goes far deeper than the mere agreement on rates of salary and tenure of office, important as these are. The conference which drew up the scheme recognised that "benefit would be likely to result from a closer coöperation of the local medical profession with the local authorities' schemes of medical survey or inspection and treatment," and one of the first fruits of this recognition is the working agreement, which we chronicled last week, between practitioners and civic council in the urban district of Willesden, where the two policies had been allowed to grow apart until reconciliation became difficult and tedious. In Portsmouth there has been no such divergence, although the sanitary authority is keen. In many other places similar divergence must have arisen if the advocates of both policies had been as keen as they were at Willesden. Within the British Medical Association itself there will now be the reconciling influence. A great opportunity has not been lost.

CANCER FACTS AND CANCER THEORIES.

FOR hundreds of years cancer has occupied the attention of physicians and surgeons, and it would be impossible to estimate the expenditure of time and energy on this absorbing subject since the doctrine of cellular pathology was first developed. It would be too much to hope that this labour has always been wisely directed or accurately performed. Much of it has resulted in knowledge which is permanent, but much more has clogged the literature with doubtful if not inaccurate statements, so that year by year the subject becomes more obscure, and the modern investigator finds his task not always lightened by the work of his predecessors, and rendered sometimes more difficult. Numberless examples of this could be quoted, but two will suffice. What are the actual results of operation in, say, cancer of the breast? What is the proportion of absolute cures, and how do the modern operations compare with the old, either as palliative or curative measures? Accurate answers to these questions are difficult to obtain, and, furthermore, there is a tendency for the written word to be forgotten though the personal impression survives; and the natural optimism of the human race connives only too readily in the conversion of the possible into the probable. Again, on the academic side, is the endothelial cell as prone to neoplastic transformation as the literature of recent years would lead one to suppose? It is, of course, a matter of some importance in view of the possibility that cancer may be due to some circulating substance, virus, hormone, or what not; but who shall say when histologists disagree? The situation is not improved by that sinister influence, often exercised by teratology on its votaries, which demands the elaboration of theories. It is impossible to contemplate with equanimity the sum of human endeavour which has been squandered in supporting or disproving unworthy theories.

Modern experimental methods are throwing on the cancer problem a light which bids fair to be powerful enough to illuminate its darkest corners, and one cannot read the article by the Director of the Imperial Cancer Research Fund, which appears in this issue, without experiencing a thrill of expectation. The elaboration of a technique by which cancer can be produced practically at will, combined with other methods of biological research, such as tissue culture, must undoubtedly and in the near future lead to most important results. Already theories which for generations have dominated certain schools of pathology are in process of demolition. The vague conception of "tissue tension" by which the disappearance of a hypothetical physiological influence of one tissue or another was held to explain the origin of malignant growth is untenable in view of the modern conception that the cancer cell differs from its progenitor in the acquirement of an actual positive property, that of continuous proliferation, though the stimulus to this may be no longer active. And the behaviour of the malignant and innocent cells during propagation outside the body shows conclusively that anaplasia as described by v. HAUSEMANN does not really exist. There is no true assumption of embryonic character by the malignant cell, and no specific loss of differentiation. At the same time the actual facts of human and experimental pathology which have hitherto been inexplicable are rapidly becoming clarified. Isolated observations which have meant little or nothing in themselves are being dovetailed one into the other, and our conceptions of what constitutes the malignant process are becoming firmer and more clearly cut every day.

The most significant aspect of the new work, however, is that which indicates the presence of a profound systemic or constitutional change in the individual in whom a malignant growth has developed. That such a change occurs is shown by the failure of animals in which a malignant growth has spontaneously occurred, or has been produced experimentally, to react in the usual way to fresh applications of tar. There seems to be quite definitely a high degree of resistance to the development of a second tumour, and though the experimental observations are few they fall into line with the facts of human pathology. It is common knowledge, for example, that multiple or even double primary malignant tumours in the same individual are rare. Unless we conceive the possibility of the simultaneous action in different parts of the body of different cancrogenic influences, the development of one tumour must be inimical to the growth of another. What constitutes this resistant state is as yet quite obscure—its presence can be recognised experimentally, but there is nothing to indicate in what it consists. Nevertheless, we are justified in believing that the next few years will see the question answered, with results in the diagnosis and treatment of malignant disease which could not even have been foreshadowed a very few years ago.

◆

CHILD MORTALITY IN SCOTLAND.

THE rates of infant and child mortality in Scotland for a series of years up to and including 1922 are given in the fourth annual report of the Scottish Board of Health, recently issued and summarised on another page of our present issue. We note that in the three years 1919–21 the rate of infant mortality averaged 94 per 1000 births in Scotland, as compared with 84 in England and Wales. The only partial participation of Scotland in the degree of reduction of infant mortality secured in England is obviously a subject deserving of careful study. In both countries the rule holds good: that a high rate of infant mortality is associated in the same community with a high death-rate in children over 1 and under 5 years of age. Thus in the experience of Scotland as a whole, in 1915 an infant death-rate of 126·5 was associated with a death-rate at ages 1–5 of 22·5, while in 1921 an infant death-rate of 90·3 was associated with a death-rate at ages 1–5 of 12·4. A valuable table given in an appendix to the report shows the variations in, and by implication, the degree of preventability of infant mortality in different parts of infancy. Thus, at ages 6–12 months infant mortality per 1000 births varied from 4·1 in Perth to 26·5 in West Lothian, and from 32·1 in Hamilton to 14·4 in Dunfermline. Similarly at ages 3–6 months there were variations between 8·2 in Sterling and 23·8 in Kincardine, and between 9·7 in Clydebank and 27·0 in Aberdeen. At ages 1 to 3 months in towns with a population of over 20,000 infant death-rates varied from 6·3 (Hamilton) to 22·3 (Aberdeen), and at ages between one week and under a month from 26·4 in Perth to 6·9 in Kirkcaldy. At ages under one week the highest death-rate was 36·1 in Kilmarnock, and the lowest, 19·8, in Port Glasgow. It may be surmised that owing to inaccuracies of registration of age at death there may have been some transfer between deaths under one week and deaths in the next three weeks of extra-uterine life; but allowing for this, the variations in local incidence of infant mortality in successive parts of infancy are very striking, and show the need for further investigation. The figures point unmistakably to the preventability of a large part of the current infant mortality in the earlier months after birth.

Annotations.

"Ne quid nimis."

THE MUSEUM OF THE COLLEGE OF SURGEONS.

The most noteworthy event recorded by Sir Arthur Keith, conservator of the museum of the Royal College of Surgeons of England, in his recent annual report is the completion of the series of specimens which illustrates the principles of pathology —the great series which is now exhibited on special stands on the floor of Room III in the museum. In 1910 Prof. S. G. Shattock and Mr. Cecil Beadles began to select, arrange, and catalogue specimens for this purpose, and now, for the first time, a complete and systematic treatise on disease has been compiled, not in words, but in illustrative specimens. The work was broken into by the war, and subsequently by the high prices charged for museum materials, but in the spring of the present year the series of general pathology was completed. The scope of this section of the museum is now fixed; if changes are made in the future they will have to be done by replacement rather than by addition. The re-arrangement, re-mounting, and re-cataloguing of that department of the museum which illustrates disease of the various parts, organs, and systems of the human body is now being undertaken. During the year a special room was provided to house and exhibit the War Office collection of medical specimens—now known as the Army Medical Collection—which had been handed over to the custody of the College. During the last 12 months 370 specimens have been mounted and added to this collection and considerable progress has been made with its cataloguing. The series of teratology and of human osteology have received valuable additions during the year, and the mounting and arrangement of the material of the Onodi collection has made good progress. The preparation of a new catalogue of the human remains preserved in the museum, a task undertaken by Miss M. L. Tildesley, working under the Council of Scientific and Industrial Research, is still in progress. The completion of this work, which involves much labour and research into records, is regarded by the conservator as most important in view of the desirability of arranging the human remains at our disposal in a proper time sequence, in order to study structural changes in succeeding periods, and an appeal has been made to the Council of Scientific and Industrial Research to have Miss Tildesley's appointment renewed for at least another year. Reports on various human remains submitted to the College for examination have been made during the year and facilities have been afforded and material supplied to investigators in various fields. In a brief report from the curator of the physiological department of the museum, special attention is drawn to a series of eel larvæ presented by Dr. Johannes Schmidt in illustration of his important researches on the peculiar and till recently unknown breeding habits of this fish, among other recently acquired specimens. Mr. Alban Doran has almost completed the descriptive catalogue of the collection of surgical instruments in the possession of the College, a task to which he has given 12 years of his life. He is now engaged on the last section of the collection—the surgical instruments used by barbarous and semi-civilised peoples. 11,688 students and visitors used the museum during the past year. Specimens recently added to the museum will be on view in Room I from Oct. 8th until Nov. 5th next.

NEW DIRECTOR-GENERAL OF THE NAVAL MEDICAL SERVICE.

It has been officially announced that Surgeon Rear-Admiral Joseph Chambers will succeed Surgeon Vice-Admiral Sir Robert Hill as Director-General of the Medical Department of the Royal Navy on Oct. 1st. Sir Robert Hill, whose retirement will be received with regret, before his appointment some four years ago was Principal Medical Officer in the Grand Fleet, serving under both Lord Jellicoe and Lord Beatty. His excellent organisation at the Battle of Jutland received special commendation, and was recognised by his promotion to the rank of Deputy Surgeon-General. He was many times selected as medical officer on the ships which have carried the King and Queen when Prince and Princess of Wales on tours to India and the colonies.

Surgeon Rear-Admiral Joseph Chambers, who has had much administrative experience at Haslar, was appointed in 1908 health lecturer at the home ports, and later took over the charge of the Naval Hospital at the Cape of Good Hope. In 1913 he was appointed medical officer of the cruiser *Suffolk*, the original flagship during the war of the late Admiral Cradock, and in 1915 was transferred to Chatham Hospital. Since October last he has been in charge of Plymouth Hospital. We congratulate him on the high charge to which he has now been appointed.

OUTBREAKS OF SEPTIC SORE-THROAT SPREAD BY MILK.

Outbreaks of sore-throat, usually accompanied by other complications, spread by contaminated milk and due to streptococci, although not very common are yet sufficiently numerous to warrant careful consideration. Nearly all the earlier outbreaks were reported in this country, and Savage,[1] in 1912, gave particulars of 18 outbreaks in Great Britain. Since that date few further outbreaks have been reported here, but a considerable number has occurred in the U.S.A., many of which have been very extensive and have been studied in considerable detail. Notable American outbreaks are those in Boston, Chicago, and Baltimore. The pioneer scientific work upon the relationship between mastitis in the cow and human disease was done by Savage between 1906 and 1909, and is contained in three reports made to and published by the Local Government Board.[2 3 4] His views as to the relationship were summarised in a paper read before the Epidemiological Section of the Royal Society of Medicine, in February, 1911.[5] While in common with earlier continental workers he found that the ætiological factor in most cases of bovine mastitis was invasion by streptococci, he carried the subject further and differentiated between the types present. It is a striking fact that while on the one hand bovine mastitis is a widely prevalent condition and the importance of excluding from the milk-supply all the milk of infected animals is not well realised or acted upon, on the other hand, outbreaks of septic sore-throat from milk are rare. Savage was able to demonstrate that the ordinary type of streptococcus (*Streptococcus mastitidis*) associated with bovine mastitis is non-pathogenic to mice and other rodents, readily sets up mastitis in experimental goats, but fails to set up disease when inoculated upon the human throat. In contra-distinction the streptococci associated with human sore-throat possess a considerable pathogenicity for mice and guinea-pigs, but do not readily set up mastitis in goats. In one case, however, a streptococcus was isolated from a case of bovine mastitis which was of the human type. From his extended investigations Savage advanced the hypothesis which may be stated in his own words (1911): "Briefly stated, I regard the bovine udder and teat lesions, as commonly met with, as of purely bovine origin and, as such, harmless to man. Occasionally, either as an invasion superadded upon the original bovine lesions or as a primary infection of the milk-organs, there is a local infection with organisms of human origin. In such cases the conditions present may be decidedly prejudicial to man. In other words, the cow, in this class of infections, is only potentially pathogenic to man when it acts as an active or passive carrier of organisms of *human* origin."

[2] Report of the Medical Officer, L.G.B., 1906–07, pp. 205–252.
[3] Ibid., 1907–08, pp. 359–424. [4] Ibid., 1908–09, pp. 294–315.
[5] Proc. Royal Soc. of Med., Epidemiological Section, 1911, iv., 73.

Since that date these conclusions have been very completely confirmed by extensive work in America, but conducted upon rather different lines. This work has mainly been in the direction of further differentiation of the types of streptococci found, particular attention being paid to their hæmolytic properties. For example, Theobald Smith and J. H. Brown[6] studied the streptococci isolated from certain milk-borne epidemics of tonsillitis in Massachusetts, in 1913 and 1914, and drew attention to the hæmolytic character of the strains responsible for the outbreaks, while they found the ordinary bovine streptococci to be non-hæmolytic. Their hæmolytic properties (β-type) are also different from those of the common throat streptococci (α-type). Other investigators, e.g., Davis,[7] have shown that hæmolytic streptococci may be found in many different types of milk and that these may differ from human hæmolytic streptococci in their being non-virulent to rabbits. The mere fact that they are hæmolytic does not establish their human origin. That hæmolytic streptococci of human origin may set up bovine mastitis in cows was shown by Davis and Capps[8] by direct experiment, the mastitis lasting for several weeks in the experimental cows, this time roughly corresponding to the duration of milk-borne epidemics. Jones[9] [10] [11] showed that both hæmolytic and non-hæmolytic types of streptococci may set up bovine mastitis, the human type producing the more severe inflammation. He also showed that a milker may readily carry streptococci on his hands from an infected to an uninfected cow. These and other investigations show that the differentiation of streptococci of human and bovine type, like all streptococcus classifications, is complicated and difficult and is not merely a question of hæmolytic ability. Other tests have been advanced, both by Savage and by the American workers. Avery and Cullen[12] have shown the advantage of determinations of hydrogen-ion concentration in glucose-broth cultures. Cultural sugar tests are also of importance. With present knowledge it would appear that, while no one test is conclusive, by employing a large series of differentiating characters it is possible to give an opinion with considerable certainty as to the type (human or bovine) of streptococcus present in a milk-spread outbreak. Brown and Orcutt[13] have found it possible in an outbreak in Boston in 1917 to identify the particular infective strain from the mastitis fluid with that from the sore throats of the sufferers.

The most recently recorded outbreak of septic sore-throat spread by milk is in Portland, Oregon, and is described by Benson and Sears.[14] The outbreak, which took place in March, 1922, was extensive, comprising 487 cases with 22 deaths. Almost all the cases drank milk from one particular dairy, which supplied non-pasteurised milk. The dairy supplied about 1200 persons, so a considerable number escaped infection. The mortality-rate was 4·3 per cent. It was ascertained that cows with diseased udders were kept in their regular stalls along with the healthy animals and in some instances only the milk from the diseased quarter was excluded from the milking. From one cow suffering from mastitis the authors isolated a streptococcus which they considered from its characters to be a human strain and which, as regards its virulence to rabbits and white mice, was of that type. It was identical with streptococci cultivated from the patients. Hæmolytic streptococci were isolated from only one of the milkers. This man had large red tonsils and gave a history of a mild sore-throat. They consider that this milker was responsible for the infection of the diseased cow's udder, that she developed a mastitis of human streptococcic origin in one quarter and that the milk of this cow was at some time included by mistake in the whole milk of the herd. The weak link in the argument is that the date of the examination of the milker is not given and no evidence is advanced to show that the milker might not have been a sufferer from consuming infected milk rather than the indirect cause of the outbreak.

THE CENTENARY OF THE EDINBURGH VETERINARY COLLEGE.

THE dawn of veterinary science in the north of Great Britain was due almost entirely to the dogged and persistent efforts of William Dick. For nearly 40 years he laboured in the teaching and demonstrating of animal diseases and ailments, and starting with a small class in Clyde-street he saw his efforts, after many struggles and vicissitudes, crowned with success in the establishment of the Dick Veterinary College. An interesting and well-written history of this Veterinary College, by Dr. O. Charnock Bradley, its principal, has just been published.[1] Since Dick's death the College has had several stalwarts associated with its activities and teaching. T. Strangeways, W. Williams, T. Walley, J. R. U. Dewar, and the great financial helper, Alexander Inglis Maccallum, have all been fine characters and men of mark. Many successful practitioners scattered over the United Kingdom and the colonies have emanated from the College and now the successor of the Clyde-street building at Summerhall will compare favourably with any veterinary college or school in the world. The book has some excellent photographs of the men who laid the foundations of veterinary science. A centenary fund is about to be inaugurated to found a post-graduate fellowship in veterinary science and the proceeds of the sale of this book are to go to the fund.

AN EPIDEMIC OF ERYTHEMA NODOSUM.

THE view that erythema nodosum is nothing more than a rather obscure manifestation of tuberculosis finds no support in the fact that now and then this eruption occurs in epidemics unrelated to any possible source of tuberculous infection. Such an epidemic has been reported by Prof. E. Ledoux in the June number of *Revue de Médecine*. In a school of midwifery 20 probationers were accommodated in a dormitory, along the walls of which some of the beds were placed. Other beds were in the centre of the dormitory, and it was a very significant fact that all the probationers developing erythema nodosum were accommodated in the central beds, which were close together. The first patient, aged 22, had been subject to frequent attacks of slight tonsillitis. On Dec. 9th, 1921, she attended a confinement, during which she felt perfectly well. On the 10th she developed a sore-throat, and in the evening of the same day an attack of shivering was accompanied by a violent headache and a high temperature; for some days it ranged from 38·5° C. to 40° C. There was no cough, and the urine was normal. Typical erythema nodosum developed on the 13th, when it first appeared on the legs. A day later some nodes also appeared on the arms. The temperature returned to normal on Dec. 21st, but during Jan. 21st, 22nd, and 23rd, and again during Feb. 3rd, 4th, 5th, and 6th, there were attacks of what seemed to be rheumatic fever, a temperature of 40° C. being associated with painful swelling of the knees and ankles. The next patient, aged 22, suffered for two or three days from slight headache and general malaise, but she was not at first ill enough to give up work. On Dec. 18th the headache became violent, and two days later there was an extensive eruption of erythema nodosum on the legs and arms. Three or four days later some nodes appeared on the face, and there was slight conjunctivitis on the left side. On Dec. 25th one knee became swollen and very painful. A blood culture proved negative. The third probationer fell ill on Jan. 1st, 1922, with headache and a temperature of 38·7° C. Next day erythema nodosum appeared on the legs, and on the 3rd there was an attack of epistaxis; the headache was now less severe. By the 11th she was convalescent, but on the 13th the temperature rose to 40·3° C., and the knees and ankles became swollen. The fourth probationer fell ill in the middle of January, when one erythematous node appeared on the left leg. She remained at work for four days, suffering only from slight lassitude. On the fifth day, however, the temperature rose to 39·5° C., and she complained of severe headache. An extensive outbreak of erythema nodosum now appeared on the limbs, and she was ill for 15 days with a high temperature. Convalescence was protracted and complicated by pain in the joints, lasting several weeks. Only the first patient suffered from a sore-throat at the beginning of the illness, but all four complained of severe headache and general malaise. In no case was there any family or personal history of tuberculosis, and there was no other evidence of tuberculosis.

STERILISATION OR SEGREGATION.

In a recent pamphlet entitled "Sterilisation and Mental Deficiency" (2*d.*) the Central Association for Mental Welfare include a considered report by their standing medical committee on the question of the surgical sterilisation of mental defectives, referred to them by the council of the Association in June, 1922. The report does not discuss legal or ethical considerations, but only the medical and biological problems involved. The provisional conclusion arrived at is that the sterilisation of defectives is not under existing conditions a practical policy, though it may be applicable to individual cases.

To effect sterilisation in either sex the surgical operations in common use are the following: (1) Vasectomy in the male; (2) salpingectomy or ovariotomy in the female. The evidence shows that vasectomy is a very simple and safe operation, that it effectively prevents procreation, and that it does not interfere with the physiological equilibrium of the individual. The operations necessary in the female are of a more serious nature and involve all the risks pertaining to an abdominal operation, as much risk perhaps as a simple operation for appendicitis. Ovariotomy interferes with the physiological equilibrium. Either operation prevents propagation. Sterilisation is recommended by its advocates for two main purposes: (*a*) With the object of ameliorating or curing certain abnormal or perverted sexual tendencies and improving the mental condition and character of the individual; (*b*) with the object of eradicating or preventing the spread of mental defect. The first of these objects would not be attained by the comparatively simple operations mentioned, and the committee regard the evidence as to individual improvement from the more serious operations of removal of the testes and ovaries as inconclusive. With regard to the racial effect of sterilisation in preventing mental deficiency, they draw attention to the following points. Excluding cases of mental defect which are not germinal in origin, but which are a consequence of accident or disease acting directly on the individual and are not transmissible, the weight of the available evidence is to the effect that although the fact of the transmission of mental defect by mentally defective parents is undoubted, a proportion only of mental defectives are the offspring of obviously defective parents. The majority are either the children of parents who appear to be normal, although frequently "carriers," or of those suffering from [illegible] mild degree of mental or physical [illegible] is not certifiable. [illegible] were all sterilisable [illegible] would not be [illegible] be effected to a partial extent. [illegible] in itself [illegible] partial prevention is [illegible] is, however, another aspect of the question. [illegible] proportion of mental defectives [illegible] their defect. [illegible] propensities or social incapacity [illegible] care necessary. [illegible] lessened by their sterilisation, and [illegible] segregation is [illegible] propagation and the best means of dealing with the social failures of the individual. It is regarded by the committee as a [illegible] procedure. [illegible] sterilisation of certifiable mental defectives might lead to a false sense of security and result in a large number of defectives who should be segregated being set at liberty. Sexual assaults, promiscuous sexual intercourse, and a direct increase in the incidence of venereal diseases and their sequelæ might be expected to ensue.

The committee add a note regarding the operation of sterilisation laws in the United States of America, where such laws have been enacted since [illegible] in 15 States. In five of these the law has been declared to be unconstitutional; in one (New York) it has been definitely repealed; in four the law is practically a dead letter; in three it is still being used, but only to a very limited extent; and in two only (California and Nebraska) is it said to be made use of at all extensively. The largest number operated upon has been in California (255[illegible] cases); these have been chiefly males, who were at the time inmates of State institutions, and no particulars are available regarding their subsequent career.

As an outcome of the report of this medical committee, the members of which include Dr. G. A. Auden, Dr. Helen Boyle, Dr. H. B. Brackenbury, Dr. Cyril Burt, Dr. R. H. Cole, Dr. [illegible], Lord Dawson, Colonel F. E. Fremantle, M.P., Dr. [illegible] Gill, Dr. G. B. Griffiths, Sir Frederick Mott, Dr. C. S. Myers, Dr. W. A. Potts, Dr. F. C. Shrubsall, Dr. A. F. Tredgold, Dr. F. D. Turner, and Dr. Meredith Young among others, the Central Association for Mental Welfare has formed the following conclusions: (1) That segregation is the best method of dealing with certifiable defectives who cannot adapt themselves to the existing social code; and (2) that judicious and kindly supervision is the best method of dealing with those not possessed of marked anti-social propensities. It is considered that these are the foundations upon which a satisfactory national scheme for dealing with the problem of mental defect may be built up.

LINITIS PLASTICA.

Dr. Albert F. R. Andresen[1] of the Gastro-Enterological Department of the Long Island College Hospital, who reports two illustrative cases in women aged 38 and 57, in whom the diagnosis was confirmed by autopsy, remarks that the term linitis plastica was first used by Brinton in 1854 to describe a diffuse increase in the connective tissue of the stomach and characterised clinically by an insidious onset, slowly progressive cachexia, and fatal termination. The most exhaustive study of the disease since Brinton's time was made by H. M. Lyle in 1911, who collected 131 cases from the literature to which he added one of his own. Linitis plastica is a disease occurring in persons of the carcinoma age, nearly all the cases on record being between the ages of 40 and 60. Males are affected twice as often as females. Usually there is some previous history of ætiological significance, such as cardio-vascular disease, alcoholism, gastric ulcer, syphilis, tuberculosis, or occupational trauma. The symptoms are not characteristic but are merely those of the achylia gastrica which is usually present, and consist in anorexia, nausea, upper abdominal discomfort or pain, vomiting, alternate constipation and diarrhœa, and more or less intense secondary anæmia. Hæmatemesis is rare. A feeling of fullness after ingestion of even small quantities of food is very suggestive, being a direct result of the actual diminution in size and loss of elasticity of the walls, as is also vomiting or regurgitation of any excess above a certain amount. Ascites may develop later. In advanced cases a sausage-like tumour may be felt lying transversely in the epigastrium. On inflating the stomach or injecting water into it through a tube the air or water may be felt gurgling rapidly through the tumour. Test-meal examination shows the rapid emptying of the stomach and the absence or reduction of hydrochloric acid. Fluoroscopic examination reveals a small hypermotile stomach, the barium mixture passing rapidly across the upper abdomen and filling the intestinal coils. The prognosis is not good, as even after removal of the gastric focus there may be progressive changes in the colon, rectum, and small intestine, causing stenosis. The average length of life in the benign cases is four years, and in the malignant two years. Treatment consists in gastrectomy, either primarily or in advanced cases, after a primary jejunostomy to improve the patient's nutrition sufficiently to make him fit for operation. In cases where the pylorus is sufficiently patent to admit the passage of a tube duodenal feeding is indicated before the operation.

"LEAVING IT TO NATURE."

When there is a miscarriage of justice and an innocent person is in prison for many years, the community to which he belongs stands aghast in sympathetic horror. Medicine being a far more complicated matter than the law, it is, unfortunately, inevitable that serious medical errors—some only errors of omission—are often made, condemning the victim to years of invalidism and misery. Of late years there has been a healthy movement in this country as well as on the Continent to shun the omniscient pose and to reduce the incidence of future blunders by giving past blunders publicity—or as much publicity as the courage and conscientiousness of the blunderer permit. In *Le Scalpel* for June 16th Dr. de Harven, of Brussels, has recorded an instructive case which is probably not unique. The patient was a woman, aged 52, who had given birth to three infants, and whose last confinement 15 years earlier had been followed by severe puerperal fever. She was confined to bed by this illness for six weeks, and the vaginal discharge continued to be profuse and purulent; she suffered from general weakness and amenorrhœa. Exactly a year after her last confinement the purulent discharge suddenly ceased, the abdomen became painful, particularly in the left iliac fossa, and there was a rise of temperature. The practitioner who was consulted diagnosed a hernia; his offer to operate on it was rejected. At this stage the patient herself could feel a hard, painful swelling, of the size of an egg, above the pubes, a little to the left of the middle line. This swelling was evidently the uterus distended by pus, which, owing to obliteration of the cervical channel, could not escape as before through the vagina. The patient was very ill and emaciated at this stage, but she gradually became a little better, being able to drag herself about. She could not run or exert herself in any way; even slight movements provoked abdominal pain, and merely walking upstairs distressed her. For 14 years she dragged out this painful existence, the slowly growing tumour in the abdomen becoming more and more troublesome and painful. While she was convalescing from an attack of influenza, she suddenly experienced excruciating pain in the abdomen, and during the next few days there was incessant vomiting with fever and other alarming signs. After this state of affairs had lasted seven weeks and she was practically moribund, she was seen for the first time by Dr. de Harven, who found a swelling, as large as an adult's head, in the lower abdomen and in the middle line. It was dull on percussion and tender. The cervix was small and hard, and there was no discharge from it. On laparotomy the swelling was found to consist of the much distended uterus which was adherent to the anterior abdominal wall. The Fallopian tubes were normal, and the ovaries were small and hard. Detachment of the adhesions between the uterus and the abdominal wall set free a veritable flood of green, creamy pus, containing streptococci, and there proved to be more than a litre and a half in the uterus. Subtotal hysterectomy was performed, and though recovery was complicated by severe suppuration, she ultimately recovered, being restored to complete health—after 15 years of misery. Apparently the influenza had stirred the streptococci into renewed activity, and the agonising pain experienced some weeks before the operation was evidently due to perforation of the uterus. Fortunately the pus became localised by adhesions and did not spread throughout the abdominal cavity. The walls of the uterus were about five times as thick as normal and had undergone fibrotic changes. Within this dense fibrous capsule the lymphatics of the uterus had evidently been compressed, and thus the enormous bag of pus within the uterus had become effectively isolated, and the uterine appendages had remained practically normal. It is probable that the patient had acquired considerable immunity to the invading streptococci, for without such immunity she could hardly have survived the severe suppuration following the operation.

OPHTHALMOLOGICAL TRAINING FOR MEDICAL STUDENTS.

We have received from the Council of British Ophthalmologists details of correspondence which passed between that Council and the Registrar of the General Medical Council in the first half of the present year. In March the Council of British Opthalmologists drew the attention of the General Medical Council to statements in the final report of the Departmental Committee on the "Causes and Prevention of Blindness," which had recently been published, to the effect that the "inadequate knowledge of diseases of the eye possessed by the large majority of the medical profession on admission to the Register" is largely due to the limited training in this subject which they receive as medical students, that few universities and examining bodies in Great Britain require candidates for a qualifying degree or diploma to be examined in ophthalmology, and that although questions on ophthalmic surgery are occasionally included in a paper, or in the oral examination, these cannot be considered as an adequate test of the candidate's knowledge of this subject. The Committee further stated that in their opinion no licence to practise medicine should be granted without satisfactory evidence of an adequate knowledge of diseases of the eye. The Council of British Ophthalmologists pointed out that this recommendation of the Departmental Committee coincided with their own previously expressed views, and encouraged them again to urge the General Medical Council to insist, by means of an examination in ophthalmology, on a uniform standard of knowledge in this subject. The General Medical Council's ruling of May, 1919, laid it down that every student should be required to attend a course of practical instruction in ophthalmology of not less than 10 weeks' duration, and that no student should be admitted to the final examination unless he produced a certificate testifying to such attendance and to a satisfactory standard of work. To this the Council of British Ophthalmologists objected on the ground that the arrangement left the evidence of satisfactory work entirely to the discretion of the ophthalmic surgeon in charge, and that in the London medical schools the evidence of satisfactory work was receiving very different interpretations. "In one school every student is now required to pass an examination before his certificate is signed, in others mere attendance in an ophthalmic department is recognised as sufficient." This difference, they stated, engendered a feeling of injustice amongst students of different schools, and was unsatisfactory from the point of view of uniformity in the standard of requisite knowledge. The experience of the Irish universities and colleges showed that there was no great difficulty in conducting an examination in ophthalmology as an intrinsic part of the final examination for degree or diploma. After the recent Summer Session of the General Medical Council, the Registrar informed the Council of British Ophthalmologists that their letter had been considered by the Examination Committee of the Council, and that the greater part of the communication was printed in full in the report made by that Committee to the Council on June 1st.

Among the recommendations of the Committee adopted by the Council were the following :—

> That the Ministry of Health be informed that on May 25th, 1922, the Council made certain recommendations to the Licensing Bodies for the improvement of the medical curriculum, one of which was that each student should receive instruction, inter alia, in the diseases of the eye, refraction, and the use of the ophthalmoscope. The Council thereby anticipated the wishes of the Departmental Committee as set forth in their report, which was not published until the autumn of that year.
>
> That the Council of British Ophthalmologists be informed that it is too soon to judge of the effect of the resolution recently adopted by the Council.

It was stated in evidence before the Departmental Committee that some of the worst results of ophthalmia neonatorum occur in cases which have from the beginning been under the sole charge of a medical practitioner. It may be left to the General Medical Council, acting with the vigilant assistance of the Council of British Ophthalmologists, to terminate the condition of affairs which allows such a statement to be made.

ELEVENTH INTERNATIONAL PHYSIOLOGICAL CONGRESS, 1923.

Sir Edward Sharpey Schafer, presiding at the Eleventh International Physiological Congress, held at Edinburgh this week, noted that the several speeches of welcome, addressed to the delegates by Captain Elliot on behalf of the Government, by the Lord Provost on behalf of the City, and by the Principal on behalf of the University had become progressively more intimate, beginning with the country at large, passing to the city of Edinburgh, and ending with the University. It was his duty and pleasure, he said, to tender the most intimate welcome of all, that of British physiology. They had before them a counterfeit presentment of the greatest of all British physiologists—William Harvey—and the President asked their acceptance, as a memento of the occasion, of a medal which had been designed from this bust by Mr. Pilkington Jackson, who had also modelled the bust from Harvey's authentic portraits. The President desired especially to associate the name of Lister with the gathering in Edinburgh, partly because he was for several years professor of surgery in the University, but chiefly on account of the fact that the researches which preceded his great discovery were researches in pure physiology and were inspired by that great teacher William Sharpey, who migrated in 1836 from Edinburgh to London and to whom the speaker and many other British physiologists owed, directly or indirectly, their introduction to the science. Incidentally it was of interest that both Harvey and Sharpey were born in the same town, Folkestone, although at an interval of more than 200 years. The President then welcomed the members of the Congress on behalf of the countrymen of Harvey and Sharpey and Lister, and noted with regret the loss of 22 workers in physiology or allied subjects who had died since the last Congress was held, among them being F. A. Bainbridge. Wilhelm Hofmeister, François Franck, and Augustus Waller. It was fortunate, he said, that the president of a physiological congress was not expected to give an account of the progress of the science since the preceding meeting. The task would, indeed, be a difficult one in view of the complexity of the science and the small part of it any one person could be expected to master. There was, however, a particular subject which was arousing an extraordinary amount of interest, not only amongst physiologists and physicians, but amongst the general public. The subject concerned the internal secretion of the pancreas and was especially connected with the activities of the Toronto School. On this account the Committee of the Congress had invited Dr. J. J. R. Macleod, the distinguished professor of physiology in the University of Toronto, to lecture to the Congress on Insulin. The President then invited Prof. Macleod to read his address, of which an abridged version will be found on p. 198 of our present issue.

THE ADMINISTRATION OF THE VACCINATION ACTS.

THE present epidemic of small-pox in parts of the country emphasises the importance of securing the proper administration of the Vaccination Acts, and the necessity of ensuring that exemption from vaccination is only obtained in conformity with the law. The Minister of Health has issued to boards of guardians a statement of the legal provisions in this connexion ; cases have been brought to his notice in which statutory declarations of conscientious objection to vaccination have been accepted by vaccination officers, although they have been made by some person other than the legal guardian of the child, and various other irregularities have occurred which, he is advised, render the statutory declaration of no effect. In some districts the prosecution of defaulters has entirely ceased. The statement points out the following facts :—

> In ordinary circumstances the father is the person having the custody of a legitimate child, and the obligation therefore rests upon him unless, by reason of his death, illness, absence or inability, or for any other cause, the mother or some other person has the custody of the child. The Vaccination Act of 1907 provides that no parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act of 1867 if within four months of the birth of the child he makes a statutory declaration that he conscientiously believes that vaccination would be prejudicial to the health of the child, and within seven days thereafter delivers or sends by post the declaration to the vaccination officer of the district. It is clear, therefore, that if the father has the legal custody of a child and neglects to cause the child to be vaccinated, he is not exempt from penalty unless he himself makes a declaration of conscientious objection.

The Minister considers it important that vaccination officers should be accurately informed as to the law on this point, and that the responsibility of parents and guardians should be made absolutely clear. The statement also points out that a vaccination officer should scrutinise every statutory declaration which he receives with a view to satisfying himself that the declaration is in all respects in order, and that the duty of taking proceedings for enforcing the provisions of the Vaccination Acts is imposed upon vaccination officers without any directions from the Ministry or the guardians, but it enjoins that the guardians should ascertain from time to time whether those officers are performing these duties, and report to the Minister any case of continued neglect on the part of a vaccination officer. In present circumstances the Minister considers it essential that proceedings should be taken in every case of default.

An Order has been made under the Vaccination Acts prescribing a new form of notice of the requirement of vaccination, in substitution for Form A contained in the First Schedule to the Vaccination Order (No. II.), 1907. The effect of the Order is to eliminate from Form A the form of statutory declaration, and to provide that forms for this purpose may be obtained from vaccination officers. The Order will come into operation on Sept. 1st next, and the necessary forms will shortly be forwarded to registrars of births and deaths, and to boards of guardians for distribution to vaccination officers.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXX.—THE TREATMENT OF THE HYPERTROPHIED PROSTATE.

A man with a hypertrophied prostate presents a more difficultly soluble problem in treatment than a superficial examination of his condition would lead us to expect. On the one hand, it has now been indisputably proved that the average expectation of life is greater amongst those patients who submit to operation under modern conditions, whilst, on the other, it cannot be denied that there is an immediate mortality which is probably larger than we are apt to recognise, our judgment being influenced on the favourable side by the perusal of the results of a very limited number of master operators. The prostatic's troubles are at first purely a local mechanical disturbance of bladder action, but when the kidneys become damaged by being compelled to secrete against great pressure, a disturbance of function of every vital organ in the body supervenes. There is a toxæmia from imperfect elimination, from the effects of which no tissue can escape. The kidneys are damaged most, so that there may not be the slightest reserve on which to call to face the exigencies of the most simple operative procedure. The muscular power of the heart is diminished, whilst the lungs, partly from the lowered circulatory efficiency, and partly from the depressed power of resistance, which they share in common with all other tissues, are prone to suffer from infective lesions. The prostatic is a generally ill man, and often, despite his apparently healthy condition, is living precariously on the brink of a catastrophe, which may be precipitated, only too surely, by ill-timed or ill-advised surgical treatment.

The Choice Between Catheter Life and Operation.

Since it is exceptional for a catheter to be used for any length of time with impunity, catheter life should never be recommended, unless there is some very serious and irremovable objection to operation, such as the presence of diabetes, advanced heart disease, carcinoma, hemiplegia, or other grave illness.

At what stage of the disease does it become necessary to advise operative treatment, or, as the case may be, catheter life? The answer to this is: 1. When the obstruction to the passage of urine has thrown such a stress upon the bladder musculature as to cause it to lose its power of obliterating completely the lumen of this viscus, and of closing the orifices of the ureters during micturition. This is usually the case when the residual urine amounts to about three ounces. 2. When the patient's health is being undermined by being awakened from sleep at frequent intervals for the purpose of micturition, a condition of bladder irritability which is sometimes set up by a prostatic adenoma still small in size and not causing very great urinary obstruction. Where the residual urine is only one or two ounces, relief may be given to the patient if he follows a careful régime, avoiding exposure to cold and damp, and the use of alcohol and highly flavoured foods; he must not overwork and must have a sufficiency of sleep. But always before acceding to this line of treatment it must be determined by appropriate tests that serious general damage has not already taken place.

If, perforce, catheter life must be installed, it is preferable that the patient should have a male attendant who can carry out the necessary manipulation with all regard to aseptic dictates; but should this not be possible, the patient should receive meticulous instructions in the technique of catheterisation. Gum-elastic coudé catheters are the best. When there is little residual urine and a fair power of expulsion remains, two passages of the catheter in 24 hours will suffice, one immediately before retiring to bed. After use the catheters should be washed, drained, dried, and placed in a tube, in the bung of which is a compartment containing paraform powder, for 24 hours. Therefore two, or better three, sets of catheters, should be provided. Another method of sterilising, about equally effective and equally troublesome, is by *boiling*. The new gum-elastic catheters will stand *boiling* for a short time, 1–2 minutes. A portable boiler in which the catheters hang suspended can be obtained. As a lubricant a jelly containing tragacanth and oxycyanate of mercury is recommended. This can be obtained sterilised in collapsible tubes. When there is no voluntary power of passing urine, so that many catheters are necessary, or when the passage of a catheter is impossible or painful for the patient, it is better to make permanent suprapubic drainage under local anæsthesia, and to provide him with an attachment for collecting urine. In most patients the consideration of operative removal comes to the fore.

Examination Preliminary to Prostatectomy.

In connexion with the actual operation of prostatectomy there are certain outstanding features. The bleeding cannot be controlled exactly as it can, for instance, in a gastro-jejunostomy, whilst the total amount of blood shed cannot be foretold; a rather ragged cavity is left, during the healing of which necrosed tissue must be absorbed and throw a strain upon the excretory organs; sepsis of the cavity inevitably occurs, though to a variable degree. We must, therefore, determine, as far as we can, the reserve powers of two great systems, the circulatory and excretory. Will the heart be able to maintain the circulation after the loss of blood which must occur in connexion with the operation? Are the kidneys working up to the limit of their capacity or will they be able to carry on when the autolysed products of destroyed tissue are absorbed into the blood-stream? Will the immunity response of the patient be equal to dealing with the inevitable infection? We have no direct measure of the powers of defence to infection, but we can carry out investigations which will help us to judge of the efficiency of the circulation and excretory apparatus. We should try to ascertain: (1) The reserve power of the heart; (2) the hæmoglobin value of the blood; (3) the blood pressure; (4) the quantity of urine passed in 24 hours and its specific gravity; (5) the reserve power of the kidneys. An index of the resources of the heart is the reaction of the patient to exertion, the presence or not of dyspnœa after a moderately sharp walk or on going upstairs. We can get no exact measurement of this function in reserve; we can only arrive at a clinical impression. Loss of blood will mean increased work for the heart. The higher the blood pressure, the less able will the heart be to respond. The toxæmia which results from the damage to the kidneys, as in chronic interstitial nephritis not dependent upon disease of the prostate, affects the bone-marrow and interferes with the birth of new red corpuscles. The patient is doubly handicapped to withstand a hæmorrhage; he suffers from anæmia to begin with and is crippled in his efforts to replace the lost red corpuscles. If the hæmoglobin percentage is below 60, it is a risky procedure to attempt a prostatectomy. Polyuria with low specific gravity and low urea content points to the existence of chronic interstitial nephritis. By flooding the circulation with urea and thus throwing a strain upon the kidneys we are able to estimate their reserve power. H. Maclean's urea-concentration test is the simplest, most practical, and most reliable method of doing this. If, in response to this test, the kidneys are able to secrete urine containing 1·5 per cent. of urea, they are not likely to fail after operation, and a considerable number of cases can be operated upon, other factors being favourable, if the percentage of concentration is down even to one. The phenolsulphonephthalein test of renal function is also useful, but is less simple and reliable.

The Institution of Preliminary Drainage.

If the tests are unfavourable to operation, it is possible to improve the patient's condition so that eventually he may be submitted to it without undue risk. The secret of such treatment is to relieve the pressure against which the kidneys have to secrete, leaving the prostate in situ. This is done by an in-dwelling catheter, or by suprapubic drainage. It is astonishing what recovery will take place from this treatment. A catheter should be tried first. Suprapubic drainage should be instituted (1) if catheterisation is impossible; (2) if the urethra will not tolerate an in-dwelling catheter; (3) if there is much urinary sepsis; (4) if the period of drainage has to be a prolonged one. Ten days or a fortnight of drainage will often suffice materially to improve the urea-concentration figure, but sometimes a delay of several months is necessary before prostatectomy can be safely undertaken. A word of caution must be given about the management of cases where there is much residual urine or overflow incontinence. Evacuation of the bladder must be gradual or uræmia may quickly follow. In such patients either a catheter should be passed every four hours and a pint of urine withdrawn until the bladder is empty, when a catheter may be tied in, or, what amounts to the same thing, a catheter is tied in the urethra and the plug removed every four hours to evacuate the same amount. Should suppression of urine follow a too rapid emptying, the symptoms of uræmia may be induced to disappear by filling up the bladder again with boric lotion.

Certain complications, such as retention of urine, hæmorrhage, and epididymitis, may occur in the prostatic; space forbids discussion of their treatment. For retention a hot bath, with hypodermic of morphine gr. ½, should first be tried, followed by gentle attempts at catheterisation; aspiration above the pubes or the insertion of a self-retaining catheter into the fundus of the bladder are last resorts. Rapid removal of urine is dangerous.

The Choice of Method for Removal of the Prostate.

It is not possible to say at present which is the better of the two methods; advocates of both exist and almost equally good statistics have been published. The suprapubic operation is certainly easier and the results are in the main good. In the hands of experts the perineal operation appears to show a slightly lower mortality and to afford better opportunity of controlling hæmorrhage; certainly drainage of the septic prostate cavity is more efficient. The two great drawbacks cited against the procedure, incontinence and urethro-rectal fistula, disappear with the increasing skill of the expert. The presence of a stone in the bladder, discovered by cystoscopy, which should always be performed when practicable, indicates the suprapubic route.

The Results of Prostatectomy.

The urinary fistula, perineal or suprapubic, is usually closed within three weeks and the patient returns to a state of health unknown to him for years. Some patients, however, still complain of a certain nocturnal frequency of micturition. A much more troublesome condition is the persistence of sepsis, from which the patient never recovers. In such individuals it is probable that the kidneys were badly infected at the time of the operation. Not very commonly a stricture follows the enucleation of a prostate. The obstruction is sometimes at the triangular ligament, at others at the bladder base, and may need a cystotomy for its proper treatment. On the whole, however, it may be said that the ultimate results of removal of the prostate are extremely good. They are incomparably better than partial excisions done by intra-urethral instruments. Recently a revival of such incomplete removal has taken place, substituting the diathermic cautery for the punch or actual cautery. It would be premature to criticise the results of such a recent technique, but the indications are that, like the older methods, it has only a limited application.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT PORTSMOUTH.

THE annual summer gathering of the British Medical Association opened under ideal weather conditions at Portsmouth on Friday, July 20th, when the Representative Body held its first session in the Municipal College, adjoining the Town Hall.

CIVIC WELCOME.

At an early stage in this session the Lord Mayor of Portsmouth, Alderman F. G. FOSTER, attended to bid hearty welcome to the Association. He was introduced by the President-Elect, Mr. C. P. CHILDE, F.R.C.S., who pointed out that it was the Lord Mayor to whom, as chairman of the Education Committee, the loan of the College was due. Mr. Childe also introduced Mr. C. A. SCOTT RIDOUT, F.R.C.S., hon. local general secretary, as the pivot on which the whole meeting was to revolve. Alderman Foster said that it was his brother, the late Sir Scott Foster, who had extended the civic welcome to the Association at its last meeting at Portsmouth in 1899. He spoke of the growing public interest in health during the intervening 24 years, telling of the local wiseacre who complained of "that fool of a medical officer sniffing round, when here I have been living in Milton for 40 years and never seen a microbe." Dr. R. WALLACE HENRY, chairman of the Representative Body, said that the Association had three great aims: first, the consolidation of medical knowledge and the finding of new methods by which disease might be cured and its incidence prevented; secondly, to discover the best methods by which advances in medical science might be passed on to the public; and thirdly, to secure to those engaged in the work such conditions, economic and other, as would free them from needless anxiety and enable them to put forth their best work. It had been said that good work was its own reward; he would add that better work came from better reward.

REPRESENTATIVE MEETING, FRIDAY, JULY 20TH.

Dr. WALLACE HENRY, of Leicester, took the chair at 10 A.M. After apologies for absence and the acceptance of certain modifications in the standing orders, Mr. J. Basil Hall, M.Ch. Camb., was elected President of the Association for 1924–25, the annual meeting of 1924 to be held at Bradford. The annual meeting of 1925 was fixed for Bath. Sir David Drummond, president in 1921–22, was elected a vice-president, as also Mr. G. A. Syme, M.S., of Melbourne, chairman-elect of the Australasian Medical Congress, Dr. R. H. Todd, of Sydney, Dr. H. E. Gibbs, hon. secretary of the New Zealand branch, Dr. W. Watkins-Pitchford of Johannesburg, and Dr. D. C. Watt of Pietermaritzburg. It was announced that Sir William Macewen was going in November as ambassador to the Australasian Congress.

PUBLIC HEALTH POLICY OF THE B.M.A.

The meeting at once settled down to consider the relations between the British Medical Association and the Society of Medical Officers of Health. These had been under discussion since the Cambridge meeting in 1920, and the negotiations had resulted in the drawing up of a definite scheme described by Dr. R. A. BOLAM, chairman of the B.M.A. Council, as an agreement between the medical profession as a whole and those who have the duty of carrying out public health functions under authority. There is at present no provision in the constitution of the Association for ensuring that the opinions of members working as whole-time officers for public health authorities shall be made known directly to the Association, and the B.M.A. Council, in the course of its investigations, became convinced that it would be for the good of all if representatives of the public health service were brought into direct contact with people doing other kinds of medical work. First, the report of a conference of representatives of the two bodies was submitted for the approval of the meeting. This report runs as follows:—

Report of Conference between B.M.A. and Society of M.O.H.'s on Public Health Medical Services.

I. The Conference has reviewed the obligations and powers imposed and conferred upon local authorities by Acts of Parliament in regard to health administration and the relative position of medical officers of health and general practitioners in schemes of health services. These obligations and powers include:—

(a) Medical survey or inspection.

(b) Treatment.

II. Local authorities must give effect to their legal obligations. The extent to which they exercise their powers is in the discretion of the local authority subject to the prior approval of the appropriate central Government department. The Conference is of opinion that benefit would be likely to result from a closer coöperation of the local medical profession with the local authorities' schemes of medical survey or inspection and treatment.

III. The Conference is in general agreement with the view of the Consultative Council on Medical and Allied Services as stated in that part of paragraph 6 of its interim report which recited:—

"Preventive and curative medicine cannot be separated on any sound principle and in any scheme of medical services must be brought together in close coördination. They must likewise be brought within the sphere of the general practitioner, whose duties should embrace the work of communal as well as individual medicine."

Advice to Local Authorities.

IV. The Conference is therefore prepared to advise local authorities:—

(1) That where private general practitioners place their opinions before local authorities on any proposed scheme of medical survey or inspection and treatment, their representations should have due consideration by the local authority in order that it may be ascertained how far it is practicable or desirable to give effect to their view.

(2) That those engaged in general practice must either be prepared to accept responsibility for the treatment of such of their private patients as are discovered by medical survey or otherwise by the local authority to be in need of treatment, or they should agree that treatment should be undertaken by the local authority without regarding such medical provision as an encroachment on their practice. To this end persons found to be in need of treatment should, in the first instance, be referred to their private medical practitioner, or if they have no regular medical attendant they should be advised to consult a private medical practitioner.

(3) Private practitioners should assist local authorities by intimating their willingness or otherwise to undertake the treatment of patients discovered in the manner stated to be in need of treatment.

Centres and Clinics.

V. That practitioners, and by arrangement medical students, should have access to centres and clinics established by local authorities, in order that they may gain such experience as the centres and clinics afford.

VI. That private medical practitioners should be able to refer to clinics and centres for advice and treatment patients who would thus be most appropriately provided for.

VII. That payments or charges, if any, made in respect of medical treatment should be either voluntary or of such a character as will not deter persons from seeking advice and obtaining early treatment.

VIII. Centres and clinics should be established and administered for the benefit of:—

(a) Those who are unable, for some reason, to obtain treatment from a private doctor, and

(b) Those who, as a result of supervisory medical work undertaken by the local authority, are discovered to be ailing, and for whose ailments treatment would not be sought unless it were provided by the local authority.

But treatment at centres and clinics should be such as can be actually given therein, and should not include any treatment that makes domiciliary attendance advisable or involves a stay of more than 48 hours at any clinic where beds are provided.

Treatment by Private Practitioners.

IX. The Conference is of opinion that in the interests of harmonious working and the acquirement of clinical experience, the possibility should always be considered of clinical work done for the public health authority being carried out through the agency of private practitioners where conditions are suitable.

X. For the purpose of a better understanding, the Conference desires to state further:—

(1) That private general practitioners or consultants accepting offices under local authorities must realise that the duties of these offices require to be fulfilled strictly in accordance with the conditions of the appointments and in priority of all other engagements.

(2) That the health policy is settled by local health authorities, not only on medical grounds, but after due regard has been given to the closely-related questions of administration and finance, local conditions and other relevant considerations.

(3) That the medical officer of health should so far as possible secure the coöperation of the local medical profession in the discharge of his duties.

(4) That the final decision of the health policy must always rest with the local central authorities.

(5) That it is the duty of the medical officer of health to ensure that effect is given to the decisions of those authorities.

Scheme for Coöperation with M.O.H.'s.

This report was agreed to without further discussion. Dr. Bolam then proposed certain alterations in the constitution of the B.M.A., involving corresponding alterations in the constitution of the Society of M.O.H.'s, the whole being a contingent agreement which precluded the Society of M.O.H.'s from independent medico-political action. The recommendations of the B.M.A. Council were as follows:—

I. (a) The B.M.A. so to alter its constitution as to allow of the *direct* representation of such of its members as are in the Public Health Service, on its various governing bodies; and

(b) The Society of M.O.H.'s so to alter its constitution as to allow of the Association being directly represented on the Council of each branch and on the Central Council of the Society.

Note.—It is eminently desirable that the representatives on the Council of the Association, or Society, should be members of the other Council.

II. The Society of M.O.H.'s to continue to formulate and urge any medico-political policy that it wishes, and where such policy is of mutual concern to both the Society and the B.M.A., the Society will present that policy to the Association through its direct representatives, and when any such medico-political matter has been finally determined by the annual representative meeting all action consequent thereon shall be taken by the B.M.A. The Society shall refrain from taking any action in support of a divergent policy until after the decision of the annual representative meeting, but in the event of the Society thereafter feeling constrained to consider the taking of separate action, such action shall not be taken until the Councils of the Association and the Society have conferred together thereon.

III. As a condition of, or preliminary to any agreement on the above lines, *if desired*, a common declaration of policy on general lines to be promulgated by both Association and Society, and a common arrangement in general terms as to certain points with regard to salaries and the method of securing them to be agreed upon.

Prolonged discussion took place on this scheme, started by an amendment from Brighton, disapproving of any alteration in the constitution of the B.M.A. which would secure for certain of its members dual facilities for voting and representation. The Association, it was argued, had been built up on an individual basis, and to change this was to go back on the democratic attitude of 1902. If 1800 public health service members were given special privileges, the same would be claimed by other groups such as Poor-law, insurance, medical women, service branches, and so on. The B.M.A. Council frankly admitted the small sacrifice of democratic principle involved in the bargain, but justified it as the only practical way of preventing the public health medical service from ploughing its own lonely furrow or combining for political action with administrative branches of the health service. The meeting agreed with the Council by refusing the Brighton amendment and passing the change in constitution by the necessary two-thirds majority.

Scale of Minimum Salaries for P.H. Medical Officers.

A definite scale[1] of minimum commencing salaries for medical officers in the public health service was then put to the meeting by the chairman of the B.M.A. Council. This scale differs substantially from that submitted at Cambridge in 1920. In its earlier form current civil service bonus and yearly increases were integral portions of the scheme. In view of the present economic position these are now accepted as guiding principles but are not obligatory. The minimum commencing salary for a junior officer has been meanwhile raised from £500 to £600, inasmuch as it was shown that progressive health authorities were now requiring evidence of special experience before a practitioner could hope to get on the short list for one of the junior appointments. The M.O.H. of a large county, with a staff of nearly 30, stated that the average age of his juniors on appointment was nearly 40, and that only one of them (appointed during the war) was without special experience on appointment. The B.M.A. Council came to the conclusion that if this special experience was to be made a sine qua non for appointment, it could not be suggested that £600 was an extravagant salary, particularly as the prospect of advancement is poor. The scale as now proposed also differs in the greater differentiation in the salaries for the chief M.O.H., to begin at £800 for a population of under 35,000—the great bulk of appointments being between £800 and £1100.

Dr. BOLAM, in moving this scale, pointed out again that much had been said regarding £600 as a commencing salary for a "young raw graduate," but this term no longer described the public health service entrant, for he or she must be fully qualified (six years) plus the D.P.H. plus special experience in some department—e.g., tuberculosis, school hygiene, M. and C.W., and was then years removed from qualification. The chances of getting £1000 or over in the service were small; he put them at 1 in 8 (wishing to be moderate); Dr. C. SANDERS at 1 in 14. The motion was carried by the necessary two-thirds majority. The Council then accepted an instruction to meet representatives of local authorities and to make such alterations in detail as might be necessary to secure an agreed scale.

Amendments in the by-laws were then passed rendered necessary by the decision to admit direct representation of public health service members on the governing bodies of the Association, the following interpretation being accepted:—

The expression "public health service member" means a member of the Association who is permanently employed in the whole-time medical service (other than service at a lunatic asylum) of the council or education authority of any county, county borough, municipal borough, metropolitan borough, burgh, urban district, rural district, or parish, or port sanitary authority in the United Kingdom.

Medical Defence for Members of the B.M.A.

On a motion by Warrington and St. Helens—

regretting that the B.M.A. Council had not seen its way to recommend the alteration of the Articles of the Association so that this paramount duty might be undertaken either by the Association itself or by its incorporation with one or

[1] *Minimum Commencing Salaries for Public Health Medical Officers.*

RESIDENT MEDICAL OFFICERS .. .. .. DEFINITION.—These are Medical Officers employed in Hospitals, Sanatoria, or other Institutions without responsibility for the work of other Medical Officers. *Note.*—Where the Appointing Authority limits the appointment to a term not exceeding one year and not renewable, this salary shall not apply.		£350 plus emoluments.
MEDICAL OFFICERS EMPLOYED IN DEPARTMENTS. DEFINITION.—These are Medical Officers without responsibility for the work of other Medical Officers, but who shall have had at least three years' experience in the practice of their profession subsequent to obtaining a registrable qualification.	Working directly under a Senior Medical Officer.	£600
SENIOR MEDICAL OFFICERS IN CHARGE OF DEPARTMENTS—e.g., Port Sanitation, School Medical Departments, Tuberculosis Departments, Mental Deficiency Departments, Maternity and Child Welfare Departments, Venereal Disease Departments, or any other similar department or combination of departments, and Medical Superintendents of Hospitals, Sanatoria, or other Institutions. DEFINITION.—These are Medical Officers who are in charge of departments and are directly responsible to the Medical Officer of Health or otherwise.	Without Assistants.	£750
	With 1 Assistant	£900
	2	£950
	3	£1000
	4	£1050
	5–6	£1100
	and for every completed two or less.	an additional £50
DEPUTY, OR CHIEF ASSISTANT, MEDICAL OFFICERS (Hospitals, Sanatoria, or other Institutions and Departments).		A salary equal to 60 per cent. of the salary of the Medical Superintendent or Senior M.O. in charge but not less than the salary of a M.O. employed in a department.
DEPUTY OR ASSISTANT MEDICAL OFFICERS OF HEALTH. DEFINITION.—A Deputy or Assistant Medical Officer of Health is a medical officer duly appointed as deputy or assistant medical officer of health by the local authority to assist the medical officer of health in the general administration of the health department and the carrying out of the various Acts, by-laws, orders, rules, regulations, &c., required to be or usually administered by the medical officer of health; the title deputy assistant medical officer of health to be limited to medical officers carrying out these general duties.		A salary equal to 60 per cent. of the salary of the M.O.H. but not less than the salary of next grade of medical officer in the department.

—	Population.	Minimum commencing salaries per annum.
MEDICAL OFFICERS OF HEALTH	Under 35,000	£800
	,, 50,000	£900
	,, 75,000	£1000
	,, 100,000	£1100
	,, 150,000	£1200
	,, 200,000	£1300
	,, 300,000	£1400
	,, 400,000	£1500
	,, 500,000	£1600
	,, 600,000	£1700
	Over 600,000	£1800

Notes.

(A) These salaries are net, any expenses necessitated by the duties being provided in addition.

(B) Population means population at the latest annual report of the Registrar-General.

(C) No existing officer should be prejudicially affected by the operation of the scale.

(D) ANNUAL INCREMENTS should be at the rate of 5 per cent. per annum, rising to 40 per cent. above the minimum basic rates.

(E) BONUS. The current Civil Service cost of living bonus should be applied to the foregoing scales.

(F) That the salaries of Medical Superintendents of Poor-law Hospitals should be as for Senior Medical Officers in charge of Departments as set out above.

(G) That salaries are to be minimum salaries for *whole-time* service.

(H) That Medical Superintendents of Institutions, and in suitable cases Chief Assistant M.O.'s, should, in addition to their salaries, be supplied with a house.

(I) That there shall be no differentiation of salary on account of sex.

(J) That all exceptional work not recognised as normal duties to the subject of additional remuneration.

(K) That if marriage be deemed by the local authority a disqualification for a medical appointment the same shall be specifically stated when the vacancy is advertised.

(L) That in placing existing officers in accordance with these salaries, years of service and merit should receive recognition.

(M) That all Medical Officers of local authorities should be subject to similar security of tenure as is provided for a Medical Officer of Health under the Public Health (Officers) Act, 1921. But where the appointing authority limits the appointment to a term not exceeding one year, and not renewable, this provision shall not apply.

became convinced that it would be for the good of all if representatives of the public health service were brought into direct contact with people doing other kinds of medical work. First, the report of a conference of representatives of the two bodies was submitted for the approval of the meeting. This report runs as follows :—

Report of Conference between B.M.A. and Society of M.O.H.'s on Public Health Medical Services.

I. The Conference has reviewed the obligations and powers imposed and conferred upon local authorities by Acts of Parliament in regard to health administration and the relative position of medical officers of health and general practitioners in schemes of health services. These obligations and powers include :—

(*a*) Medical survey or inspection.
(*b*) Treatment.

II. Local authorities must give effect to their legal obligations. The extent to which they exercise their powers is in the discretion of the local authority subject to the prior approval of the appropriate central Government department. The Conference is of opinion that benefit would be likely to result from a closer coöperation of the local medical profession with the local authorities' schemes of medical survey or inspection and treatment.

III. The Conference is in general agreement with the view of the Consultative Council on Medical and Allied Services as stated in that part of paragraph 6 of its interim report which recited :—

"Preventive and curative medicine cannot be separated on any sound principle and in any scheme of medical services must be brought together in close coördination. They must likewise be brought within the sphere of the general practitioner, whose duties should embrace the work of communal as well as individual medicine."

Advice to Local Authorities.

IV. The Conference is therefore prepared to advise local authorities :—

(1) That where private general practitioners place their opinions before local authorities on any proposed scheme of medical survey or inspection and treatment, their representations should have due consideration by the local authority in order that it may be ascertained how far it is practicable or desirable to give effect to their view.

(2) That those engaged in general practice must either be prepared to accept responsibility for the treatment of such of their private patients as are discovered by medical survey or otherwise by the local authority to be in need of treatment, or they should agree that treatment should be undertaken by the local authority without regarding such medical provision as an encroachment on their practice. To this end persons found to be in need of treatment should, in the first instance, be referred to their private medical practitioner, or if they have no regular medical attendant they should be advised to consult a private medical practitioner.

(3) Private practitioners should assist local authorities by intimating their willingness or otherwise to undertake the treatment of patients discovered in the manner stated to be in need of treatment.

Centres and Clinics.

V. That practitioners, and by arrangement medical students, should have access to centres and clinics established by local authorities, in order that they may gain such experience as the centres and clinics afford.

VI. That private medical practitioners should be able to refer to clinics and centres for advice and treatment patients who would thus be most appropriately provided for.

VII. That payments or charges, if any, made in respect of medical treatment should be either voluntary or of such a character as will not deter persons from seeking advice and obtaining early treatment.

VIII. Centres and clinics should be established and administered for the benefit of :—

(*a*) Those who are unable, for some reason, to obtain treatment from a private doctor, and

(*b*) Those who, as a result of supervisory medical work undertaken by the local authority, are discovered to be ailing, and for whose ailments treatment would not be sought unless it were provided by the local authority.

But treatment at centres and clinics should be such as can be actually given therein, and should not include any treatment that makes domiciliary attendance advisable or involves a stay of more than 48 hours at any clinic where beds are provided.

Treatment by Private Practitioners.

IX. The Conference is of opinion that in the interests of harmonious working and the acquirement of clinical experience, the possibility should always be considered of clinical work done for the public health authority being carried out through the agency of private practitioners where conditions are suitable.

X. For the purpose of a better understanding, the Conference desires to state further :—

(1) That private general practitioners or consultants accepting offices under local authorities must realise that the duties of these offices require to be fulfilled strictly in accordance with the conditions of the appointments and in priority of all other engagements.

(2) That the health policy is settled by local health authorities, not only on medical grounds, but after due regard has been given to the closely-related questions of administration and finance, local conditions and other relevant considerations.

(3) That the medical officer of health should so far as possible secure the coöperation of the local medical profession in the discharge of his duties.

(4) That the final decision of the health policy must always rest with the local central authorities.

(5) That it is the duty of the medical officer of health to ensure that effect is given to the decisions of those authorities.

Scheme for Coöperation with M.O.H.'s.

This report was agreed to without further discussion. Dr. BOLAM then proposed certain alterations in the constitution of the B.M.A., involving corresponding alterations in the constitution of the Society of M.O.H.'s, the whole being a contingent agreement which precluded the Society of M.O.H.'s from independent medico-political action. The recommendations of the B.M.A. Council were as follows :—

I. (*a*) The B.M.A. so to alter its constitution as to allow of the *direct* representation of such of its members as are in the Public Health Service, on its various governing bodies ; and

(*b*) The Society of M.O.H.'s so to alter its constitution as to allow of the Association being directly represented on the Council of each branch and on the Central Council of the Society.

Note.—It is eminently desirable that the representatives on the Council of the Association, or Society, should be members of the other Council.

II. The Society of M.O.H.'s to continue to formulate and urge any medico-political policy that it wishes, and where such policy is of mutual concern to both the Society and the B.M.A., the Society will present that policy to the Association through its direct representatives, and when any such medico-political matter has been finally determined by the annual representative meeting all action consequent thereon shall be taken by the B.M.A. The Society shall refrain from taking any action in support of a divergent policy until after the decision of the annual representative meeting, but in the event of the Society thereafter feeling constrained to consider the taking of separate action, such action shall not be taken until the Councils of the Association and the Society have conferred together thereon.

III. As a condition of, or preliminary to any agreement on the above lines, *if desired*, a common declaration of policy on general lines to be promulgated by both Association and Society, and a common arrangement in general terms as to certain points with regard to salaries and the method of securing them to be agreed upon.

Prolonged discussion took place on this scheme, started by an amendment from Brighton, disapproving of any alteration in the constitution of the B.M.A. which would secure for certain of its members dual facilities for voting and representation. The Association, it was argued, had been built up on an individual basis, and to change this was to go back on the democratic attitude of 1902. If 1800 public health service members were given special privileges, the same would be claimed by other groups such as Poor-law, insurance, medical women, service branches, and so on. The B.M.A. Council frankly admitted the small sacrifice of democratic principle involved in the bargain, but justified it as the only practical way of preventing the public health medical service from ploughing its own lonely furrow or combining for political action with administrative branches of the health service. The meeting agreed with the Council by refusing the Brighton amendment and passing the change in constitution by the necessary two-thirds majority.

refer to the consideration of the Council the following points for definite decision next year with such interim action as was within the present range of its hospital policy :—

> (*a*) The income limit scale to be such as is approved by the majority of the medical profession resident and practising within the area of the scheme.
>
> (*b*) Free choice of doctor (attendant and specialist) by patient subject to consent of doctor to act.
>
> (*c*) The scheme to be administered by a general committee representative of the interests concerned, and not by a voluntary hospital or other coöperating institution.
>
> (*d*) The method of remuneration of medical specialists to be payment for work done.
>
> (*e*) Medical remuneration for specialist's services to be what the local profession considers adequate having due regard to the services to be rendered and other conditions of the scheme.
>
> (*f*) Adequate medical representation of the General Committee administering the scheme with recognition of the Division (Branch) of the British Medical Association as representative of the profession in the area of the scheme.
>
> (*g*) The accommodation provided for in-patient treatment to be at recognised nursing homes, paying hospitals, or in *accommodation* of the nature of a nursing home in connexion with a voluntary hospital.

—these proposals being based on the fundamental points adopted for domiciliary National Health Insurance.

The British Medical Journal.

The B.M.A. Council reported that this year Sir Dawson Williams completes 25 years' editorship of the *British Medical Journal*. It was resolved and carried by acclamation—

> That this meeting sends its heartiest congratulations to Sir Dawson Williams, upon the completion of his 25 years as Editor of the *British Medical Journal*, and wishes him health and success in carrying on that work.

To signalise the occasion Sir Dawson Williams is to be the guest of the evening at the B.M.A. Council dinner on Oct. 24th.

Scientific Work of the B.M.A.
